PL/SQL is Oracle Corporation’s procedural language extension to SQL, the standard data access language for relational databases. PL/SQL offers modern software engineering features such as data encapsulation, information hiding, overloading, and exception handling, and so brings state–of–the–art programming to the Oracle Server and Toolset.

Designed to meet the practical needs of software developers, this Guide explains all the concepts behind PL/SQL and illustrates every facet of the language. Good programming style is stressed throughout and supported by numerous examples. Here is all the information you need to understand PL/SQL and use it effectively to solve your information management problems.
Figure 1 Oracle Server Documentation Set and Related Documents
Reading Guide to the Oracle7 Server Library

This section describes the Oracle7 Server library and helps you decide which manuals in the library to read. It also recommends reading paths, which are diagramed in Figure 1.

Manuals for All Users

All users should begin with the manuals at the top of the diagram, Oracle7 Server Concepts and Oracle7 Server Migration. Oracle7 Server Concepts gives a brief description of each Oracle7 feature and presents the concepts that a new user must understand before reading other manuals. Oracle7 Server Migration lists the differences between each release of the Oracle Server. Current users should read Oracle7 Server Migration before upgrading to new releases of Oracle.

Administrator and Developer Paths

After reading Oracle7 Server Concepts and/or Oracle7 Server Migration, the reading path splits into the “Database Administrator’s Path” and the “Application Developer’s Path.” Choose the appropriate path (or paths) for the tasks you need to do. For example, backing up the database is an administrative task, so it is documented in the Oracle7 Server Administrator’s Guide. However, creating stored procedures is an application developer’s task, so it is documented in the Oracle7 Server Application Developer’s Guide.

Whichever path you follow, you might need to refer to the Oracle Network Products documentation. If you use Oracle in a networked environment (either client/server or distributed database), you use SQL*Net and other network products. For more information, see your Network Products documentation.

Administrator’s Path

Typically, database administrators do a set of tasks related to the maintenance, security, and performance of the database. The manuals in the Administrator’s Path explain the role of the database administrator and describe in detail how to do administrator’s tasks.

Database administrators should become familiar with the Oracle7 Server Administrator’s Guide. This manual contains most of the information that a database administrator needs. Oracle7 Server Utilities describes the auxiliary utilities provided with the Oracle Server, such as SQL*Loader, the Import utility, and the Export Utility.
Another manual that might be useful to database administrators is the *Oracle Server Manager User’s Guide*. Server Manager is a graphical user interface for doing administrative tasks. If you are using Server Manager, you should refer to the *Oracle Server Manager User’s Guide*.

As an application developer, you should learn about the many Oracle7 features that can ease application development and improve performance.

The *Oracle7 Server Application Developer’s Guide* describes all the Oracle7 Server features that relate to application development. The *PL/SQL User’s Guide and Reference* describes PL/SQL, a high-level programming language, which is Oracle Corporation’s procedural extension to SQL. The *Programmer’s Guide to the Oracle Call Interface* describes the Oracle Call Interface, with which you can build third-generation language (3GL) applications that access Oracle.

Oracle Corporation also provides the Pro* series of 3GL precompilers, which allow you to embed SQL and PL/SQL in your application programs. If you program in Ada, C/C++, COBOL, or FORTRAN, refer to the corresponding precompiler manual. For example, if you program in C or C++, refer to the *Programmer’s Guide to the Oracle Pro*C/C++ Precompiler*.

Oracle CDE is a cooperative development environment that provides several tools including a form builder, reporting tools, and a debugging environment for PL/SQL. If you use Oracle CDE, refer to the appropriate Tools documentation.

Certain manuals provide reference material and guidance for both database administrators and application developers. After reading the appropriate manuals in each user path, you might want to refer to one of the reference manuals from time to time.

*Oracle7 Server Tuning* shows you how to diagnose performance problems and take corrective action. *Oracle7 Server Messages* lists all the messages and codes that Oracle can return. *Oracle7 Server SQL Reference* provides syntax diagrams and usage notes for all SQL used with the Oracle Server. *Oracle7 Server Reference* describes the Oracle data dictionary tables, initialization parameters, national language support features, and so on.
Manuals for Oracle Options
You can purchase the Oracle Server with several options, which are described in separate manuals. If you purchased Oracle with one or more options, besides reading other manuals in the Oracle7 Server library, you should read the manuals that describe those options. For example, the manual that describes the Parallel Server option is Oracle7 Parallel Server.

Other Information
Oracle Corporation also publishes a file commonly named README.DOC, which is available on your distribution media. This file describes differences between minor releases of Oracle software that are not documented in new manuals. The exact name and location of this file vary by operating system. Read this file to learn about software changes that are not documented in the manuals.

For system–specific information about the Oracle Server, see your installation or user’s guide and any available system release bulletins.

Audience
Anyone developing applications for the Oracle Server will benefit from reading this Guide. Written especially for programmers, this comprehensive treatment of PL/SQL will also be of value to systems analysts, project managers, and others interested in database applications. To use this Guide effectively, you need a working knowledge of the following subjects:

• a procedural programming language such as Ada, C, Cobol, Fortran, Pascal, or PL/I
• the SQL database language
• Oracle concepts and terminology
• Oracle application development tools

You will not find installation instructions or system–specific information in this Guide. See the Oracle installation or user’s guide for your system.
What’s New in This Edition?

Releases 2.1 and 2.2 of PL/SQL offer an array of new features to help you build better database applications. For example, now you can benefit from

- cursor variables, which add flexibility and let you centralize data retrieval
- the RESTRICT_REFERENCES pragma, which allows you to call packaged functions from SQL statements
- user–defined subtypes, which can increase reliability, provide compatibility, and improve readability
- SQL92 compliance, which lets you specify a column alias in the ORDER BY clause of a SELECT statement
- the PL/SQL Wrapper, which enables you to deliver PL/SQL applications without exposing your source code

For more information, see Appendix A.

How PL/SQL User’s Guide and Reference Is Organized

This Guide is divided into three parts: a user’s guide, a language reference, and appendices.

User’s Guide

This part introduces you to PL/SQL and shows you how to use its many features.

Chapter 1: Overview
This chapter surveys the main features of PL/SQL and points out the advantages they offer. It also acquaints you with the basic concepts behind PL/SQL and the general appearance of PL/SQL programs.

Chapter 2: Fundamentals
This chapter focuses on the small–scale aspects of PL/SQL. It discusses lexical units, datatypes, expressions, assignments, block structure, declarations, scope rules, built–in functions, PL/SQL tables, user–defined records, and user–defined subtypes.

Chapter 3: Control Structures
This chapter shows you how to structure the flow of control through a PL/SQL program. It describes conditional, iterative, and sequential control. You learn how to apply simple but powerful control structures such as IF–THEN–ELSE and WHILE–LOOP.
Chapter 4: Interaction with Oracle
This chapter shows you how PL/SQL supports the SQL commands, functions, and operators that let you manipulate Oracle data. You also learn how to manage cursors, process transactions, and safeguard the consistency of your database.

Chapter 5: Error Handling
This chapter provides an in–depth discussion of error reporting and recovery. You learn how to detect and handle errors using PL/SQL exceptions.

Chapter 6: Subprograms
This chapter shows you how to write and use subprograms, which aid application development by isolating operations. It discusses procedures, functions, forward declarations, actual versus formal parameters, positional and named notation, parameter modes, parameter default values, aliasing, overloading, and recursion.

Chapter 7: Packages
This chapter shows you how to bundle related PL/SQL types, objects, and subprograms into a package. Once written, your general–purpose package is compiled, then stored in an Oracle database, where its contents can be shared by many applications.

Chapter 8: Execution Environments
This chapter shows you how to use PL/SQL in the SQL*Plus, Oracle Precompiler, and Oracle Call Interface (OCI) environments.

Language Reference
This part serves as a reference guide to PL/SQL commands, syntax and semantics, coding conventions, and error messages.

Chapter 9: Language Elements
This chapter uses syntax diagrams to show how commands, parameters, and other language elements are sequenced to form PL/SQL statements. Also, it provides coding conventions, usage notes, and short examples, all of which help you become fluent in PL/SQL quickly.

Appendices
This part provides a survey of new features, sample programs, supplementary technical information, and a list of reserved words.

Appendix A: New Features
This appendix looks at the array of new features offered by releases 2.1 and 2.2 of PL/SQL.

Appendix B: Sample Programs
This appendix provides several PL/SQL programs to guide you in writing your own. The sample programs illustrate important PL/SQL concepts and features.
Appendix C: CHAR versus VARCHAR2 Semantics
This appendix explains the subtle but important semantic differences between the CHAR and VARCHAR2 base types.

Appendix D: PL/SQL Wrapper
This appendix shows you how to run the PL/SQL Wrapper, a standalone utility that enables you to deliver PL/SQL applications without exposing your source code.

Appendix E: Reserved Words
This appendix lists those words reserved for use by PL/SQL.

Notational Conventions
This Guide uses the following notation in code examples:

- Angle brackets enclose the name of a syntactic element.
- A double hyphen begins a single–line comment, which extends to the end of a line.
- These symbols delimit a multi–line comment, which can extend from one line to another.
- A dot separates an object name from a component name and so qualifies a reference.
- An ellipsis shows that statements or clauses irrelevant to the discussion were left out.

UPPERCASE Uppercase denotes PL/SQL keywords.
lowercase Lowercase denotes user–defined items such as variables, parameters, and exceptions.

In the text, the syntax of PL/SQL is described using a variant of Backus–Naur Form (BNF), which includes the following symbols:

- Brackets enclose optional items.
- Braces enclose items only one of which is required.
- A vertical bar separates alternatives within brackets or braces.
- An ellipsis shows that the preceding parameter can be repeated.

In the text, terms being defined for the first time, words being emphasized, error messages, and book titles are italicized.
Sample Database Tables

Most programming examples in this Guide use two sample database tables: *dept* and *emp*. Their definitions follow:

```
CREATE TABLE dept
  (deptno NUMBER(2) NOT NULL,
   dname  CHAR(14),
   loc    CHAR(13))
```

```
CREATE TABLE emp
  (empno    NUMBER(4) NOT NULL,
   ename    CHAR(10),
   job      CHAR(9),
   mgr      NUMBER(4),
   hiredate DATE,
   sal      NUMBER(7,2),
   comm     NUMBER(7,2),
   deptno   NUMBER(2))
```

Sample Data

Respectively, the *dept* and *emp* tables contain the following rows of data:

```
DEPTNO  DNAME      LOC
––––––– –––––––––– –––––––––
10      ACCOUNTING NEW YORK
20      RESEARCH   DALLAS
30      SALES      CHICAGO
40      OPERATIONS BOSTON
```

```
EMPNO  ENAME   JOB          MGR  HIREDATE    SAL   COMM  DEPTNO
––––– ––––––– ––––––––– –––––– ––––––––– –––––– –––––– –––––––
7369 SMITH   CLERK       7902 17–DEC–80    800             20
7499 ALLEN   SALESMAN    7698 20–FEB–81   1600    300      30
7521 WARD    SALESMAN    7698 22–FEB–81   1250    500      30
7566 JONES   MANAGER     7839 02–APR–81   2975             20
7654 MARTIN  SALESMAN    7698 28–SEP–81   1250   1400      30
7698 BLAKE   MANAGER     7839 01–MAY–81   2850             30
7782 CLARK   MANAGER     7788 23–JUN–81   2450             10
7839 KING    PRESIDENT        17–NOV–81   5000             10
7844 TURNER  SALESMAN    7698 08–SEP–81   1500             30
7876 ADAMS   CLERK       7788 23–MAY–87   1100             20
7900 JAMES   CLERK       7698 03–DEC–81   950             30
7902 FORD    ANALYST     7566 03–DEC–81   3000             20
7934 MILLER  CLERK       7782 23–JAN–82   1300             10
```
Your Comments Are Welcome

We appreciate your comments. As we evaluate and revise our documentation, your opinions are the most important feedback we receive. At the back of our printed manuals is a Reader’s Comment Form, which we encourage you to use. If the form is not available, please use the following address or fax number:

User’s Guide
Overview

The limits of my language mean the limits of my world.

Ludwig Wittgenstein

This chapter surveys the main features of PL/SQL and points out the advantages they offer. It also acquaints you with the basic concepts behind PL/SQL and the general appearance of PL/SQL programs. You see how PL/SQL bridges the gap between database technology and procedural programming languages.
Main Features

A good way to get acquainted with PL/SQL is to look at a sample program. The program below processes an order for tennis rackets. First, it declares a variable of type NUMBER to store the quantity of tennis rackets on hand. Then, it retrieves the quantity on hand from a database table named inventory. If the quantity is greater than zero, the program updates the table and inserts a purchase record into another table named purchase_record. Otherwise, the program inserts an out-of-stock record into the purchase_record table.

```sql
-- available online in file EXAMP1
DECLARE
    qty_on_hand  NUMBER(5);
BEGIN
    SELECT quantity INTO qty_on_hand FROM inventory
    WHERE product = 'TENNIS RACKET'
    FOR UPDATE OF quantity;
    IF qty_on_hand > 0 THEN  -- check quantity
        UPDATE inventory SET quantity = quantity - 1
        WHERE product = 'TENNIS RACKET';
        INSERT INTO purchase_record
            VALUES ('Tennis racket purchased', SYSDATE);
    ELSE
        INSERT INTO purchase_record
            VALUES ('Out of tennis rackets', SYSDATE);
    END IF;
    COMMIT;
END;
```

With PL/SQL, you can use SQL statements to manipulate Oracle data and flow-of-control statements to process the data. Moreover, you can declare constants and variables, define procedures and functions, and trap runtime errors. Thus, PL/SQL combines the data manipulating power of SQL with the data processing power of procedural languages.
PL/SQL is a block-structured language. That is, the basic units (procedures, functions, and anonymous blocks) that make up a PL/SQL program are logical blocks, which can contain any number of nested sub-blocks. Typically, each logical block corresponds to a problem or subproblem to be solved. Thus, PL/SQL supports the divide-and-conquer approach to problem solving called stepwise refinement.

A block (or sub-block) lets you group logically related declarations and statements. That way, you can place declarations close to where they are used. The declarations are local to the block and cease to exist when the block completes.

As Figure 1–1 shows, a PL/SQL block has three parts: a declarative part, an executable part, and an exception-handling part. (In PL/SQL, a warning or error condition is called an exception.) Only the executable part is required.

The order of the parts is logical. First comes the declarative part, in which objects can be declared. Once declared, objects can be manipulated in the executable part. Exceptions raised during execution can be dealt with in the exception-handling part.

You can nest sub-blocks in the executable and exception-handling parts of a PL/SQL block or subprogram but not in the declarative part. Also, you can define local subprograms in the declarative part of any block. However, you can call local subprograms only from the block in which they are defined.
PL/SQL allows you to declare variables and constants, then use them in SQL and procedural statements anywhere an expression can be used. However, forward references are not allowed. So, you must declare a variable or constant before referencing it in other statements, including other declarative statements.

### Declaring Variables

Variables can have any SQL datatype, such as CHAR, DATE, and NUMBER, or any PL/SQL datatype, such as BOOLEAN and BINARY_INTEGER. For example, assume you want to declare a variable named `part_no` to hold 4-digit numbers and a variable named `in_stock` to hold the Boolean value TRUE or FALSE. You declare these variables as follows:

```plsql
part_no  NUMBER(4);
in_stock BOOLEAN;
```

You can also declare records and PL/SQL tables using the RECORD and TABLE composite datatypes.

### Assigning Values to a Variable

You can assign values to a variable in two ways. The first way uses the assignment operator (:=), a colon followed by an equal sign. You place the variable to the left of the operator and an expression to the right. Some examples follow:

```plsql
tax := price * tax_rate;
bonus := current_salary * 0.10;
amount := TO_NUMBER(SUBSTR('750 dollars', 1, 3));
valid := FALSE;
```

The second way to assign values to a variable is to select or fetch database values into it. In the following example, you have Oracle compute a 10% bonus when you select the salary of an employee:

```plsql
SELECT sal * 0.10 INTO bonus FROM emp WHERE empno = emp_id;
```

Then, you can use the variable `bonus` in another computation or insert its value into a database table.

### Declaring Constants

Declaring a constant is like declaring a variable except that you must add the keyword CONSTANT and immediately assign a value to the constant. Thereafter, no more assignments to the constant are allowed. In the following example, you declare a constant named `credit_limit`:

```plsql
credit_limit CONSTANT REAL := 5000.00;
```
Cursors

Oracle uses work areas to execute SQL statements and store processing information. A PL/SQL construct called a cursor lets you name a work area and access its stored information. There are two kinds of cursors: implicit and explicit. PL/SQL implicitly declares a cursor for all SQL data manipulation statements, including queries that return only one row. For queries that return more than one row, you can explicitly declare a cursor to process the rows individually. An example follows:

```sql
DECLARE
    CURSOR c1 IS
        SELECT empno, ename, job FROM emp WHERE deptno = 20;

The set of rows returned by a multi-row query is called the active set. Its size is the number of rows that meet your search criteria. As Figure 1 – 2 shows, an explicit cursor "points" to the current row in the active set. This allows your program to process the rows one at a time.

![Active Set](Figure 1 – 2 Query Processing)

Multi-row query processing is somewhat like file processing. For example, a COBOL program opens a file, processes records, then closes the file. Likewise, a PL/SQL program opens a cursor, processes rows returned by a query, then closes the cursor. Just as a file pointer marks the current position in an open file, a cursor marks the current position in an active set.

You use the OPEN, FETCH, and CLOSE statements to control a cursor. The OPEN statement executes the query associated with the cursor, identifies the active set, and positions the cursor before the first row. The FETCH statement retrieves the current row and advances the cursor to the next row. When the last row has been processed, the CLOSE statement disables the cursor.
In most situations that require an explicit cursor, you can simplify coding by using a cursor FOR loop instead of the OPEN, FETCH, and CLOSE statements.

A cursor FOR loop implicitly declares its loop index as a record that represents a row in a database table, opens a cursor, repeatedly fetches rows of values from the active set into fields in the record, then closes the cursor when all rows have been processed. In the following example, the cursor FOR loop implicitly declares emp_rec as a record:

```
DECLARE
  CURSOR c1 IS
    SELECT ename, sal, hiredate, deptno FROM emp;
  ...
BEGIN
  FOR emp_rec IN c1 LOOP
    ...
    salary_total := salary_total + emp_rec.sal;
    END LOOP;
  END;
END;
```

You use dot notation to reference individual fields in the record.

Like a cursor, a cursor variable points to the current row in the active set of a multi-row query. But, unlike a cursor, a cursor variable can be opened for any type-compatible query. It is not tied to a specific query. Cursor variables are true PL/SQL variables, to which you can assign new values and which you can pass to subprograms stored in an Oracle database. This gives you more flexibility and a convenient way to centralize data retrieval.

After declaring and initializing a cursor variable in a PL/SQL host environment such as a Pro*C program, you pass the cursor variable to PL/SQL. Then, you OPEN it FOR a multi-row query on the server side, FETCH from it back on the client side, then CLOSE it on either side. In the following example, you pass a cursor variable to a packaged procedure, which opens the cursor variable emp_cv for the chosen query:

```
PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp, choice IN CHAR) IS
BEGIN
  IF choice = 'C' THEN
    OPEN emp_cv FOR SELECT * FROM emp WHERE comm IS NOT NULL;
  ELSIF choice = 'S' THEN
    OPEN emp_cv FOR SELECT * FROM emp WHERE sal > 2500;
  ELSIF choice = 'J' THEN
    OPEN emp_cv FOR SELECT * FROM emp WHERE job = 'MANAGER';
  END IF;
END open_emp_cv;
```
Attributes

PL/SQL variables and cursors have attributes, which are properties that let you reference the datatype and structure of an object without repeating its definition. Database columns and tables have similar attributes, which you can use to ease maintenance.

%TYPE

The %TYPE attribute provides the datatype of a variable or database column. This is particularly useful when declaring variables that will hold database values. For example, assume there is a column named title in a table named books. To declare a variable named my_title having the same datatype as the column title, you use dot notation and the %TYPE attribute, as follows:

my_title books.title%TYPE;

Declaring my_title with %TYPE has two advantages. First, you need not know the exact datatype of title. Second, if you change the database definition of title (make it a longer character string, for example), the datatype of my_title changes accordingly at run time.

%ROWTYPE

In PL/SQL, records are used to group data. A record consists of a number of related fields in which data values can be stored. The %ROWTYPE attribute provides a record type that represents a row in a table. The record can store an entire row of data selected from the table or fetched from a cursor or cursor variable.

Columns in a row and corresponding fields in a record have the same names and datatypes. In the example below, you declare a record named dept_rec. Its fields have the same names and datatypes as the columns in the dept table.

DECLARE
    dept_rec dept%ROWTYPE;  -- declare record variable

You use dot notation to access field values, as the following example shows:

my_deptno := dept_rec.deptno;

If you declare a cursor that retrieves the last name, salary, hire date, and job title of an employee, you can use %ROWTYPE to declare a record that stores the same information, as follows:

DECLARE
    CURSOR c1 IS SELECT ename, sal, hiredate, job FROM emp;
    emp_rec c1%ROWTYPE;  -- declare record variable that
                          -- represents a row in the emp table
When you execute the statement

```plsql
FETCH c1 INTO emp_rec;
```

the value in the `ename` column of the `emp` table is assigned to the `ename` field of `emp_rec`, the value in the `sal` column is assigned to the `sal` field, and so on. Figure 1–3 shows how the result might appear.

<table>
<thead>
<tr>
<th>emp_rec.ename</th>
<th>JAMES</th>
</tr>
</thead>
<tbody>
<tr>
<td>emp_rec.sal</td>
<td>950.00</td>
</tr>
<tr>
<td>emp_rec.hiredate</td>
<td>03–DEC–81</td>
</tr>
<tr>
<td>emp_rec.job</td>
<td>CLERK</td>
</tr>
</tbody>
</table>

**Figure 1–3 %ROWTYPE Record**

**Control Structures**

Control structures are the most important PL/SQL extension to SQL. Not only does PL/SQL let you manipulate Oracle data, it lets you process the data using conditional, iterative, and sequential flow–of–control statements such as IF–THEN–ELSE, FOR–LOOP, WHILE–LOOP, EXIT–WHEN, and GOTO. Collectively, these statements can handle any situation.

**Conditional Control**

Often, it is necessary to take alternative actions depending on circumstances. The IF–THEN–ELSE statement lets you execute a sequence of statements conditionally. The IF clause checks a condition; the THEN clause defines what to do if the condition is true; the ELSE clause defines what to do if the condition is false or null.

Consider the program below, which processes a bank transaction. Before allowing you to withdraw $500 from account 3, it makes sure the account has sufficient funds to cover the withdrawal. If the funds are available, the program debits the account; otherwise, the program inserts a record into an audit table.

```plsql
-- available online in file EXAMP2
DECLARE
    acct_balance NUMBER(11,2);
    acct CONSTANT NUMBER(4) := 3;
    debit_amt CONSTANT NUMBER(5,2) := 500.00;
BEGIN
    SELECT bal INTO acct_balance FROM accounts
    WHERE account_id = acct
    FOR UPDATE OF bal;
```
IF acct_balance >= debit_amt THEN
    UPDATE accounts SET bal = bal - debit_amt
    WHERE account_id = acct;
ELSE
    INSERT INTO temp VALUES
        (acct, acct_balance, 'Insufficient funds');
    -- insert account, current balance, and message
END IF;
COMMIT;
END;

A sequence of statements that uses query results to select alternative actions is common in database applications. Another common sequence inserts or deletes a row only if an associated entry is found in another table. You can bundle these common sequences into a PL/SQL block using conditional logic. This can improve performance and simplify the integrity checks built into Oracle Forms applications.

Iterative Control

LOOP statements let you execute a sequence of statements multiple times. You place the keyword LOOP before the first statement in the sequence and the keywords END LOOP after the last statement in the sequence. The following example shows the simplest kind of loop, which repeats a sequence of statements continually:

LOOP
    -- sequence of statements
END LOOP;

The FOR–LOOP statement lets you specify a range of integers, then execute a sequence of statements once for each integer in the range. For example, suppose that you are a manufacturer of custom-made cars and that each car has a serial number. To keep track of which customer buys each car, you might use the following FOR loop:

FOR i IN 1..order_qty LOOP
    UPDATE sales SET custno = customer_id
    WHERE serial_num = serial_num_seq.NEXTVAL;
END LOOP;

The WHILE–LOOP statement associates a condition with a sequence of statements. Before each iteration of the loop, the condition is evaluated. If the condition yields TRUE, the sequence of statements is executed, then control resumes at the top of the loop. If the condition yields FALSE or NULL, the loop is bypassed and control passes to the next statement.
In the following example, you find the first employee who has a salary over $4000 and is higher in the chain of command than employee 7902:

```
DECLARE
  salary         emp.sal%TYPE;
  mgr_num        emp.mgr%TYPE;
  last_name      emp.ename%TYPE;
  starting_empno CONSTANT NUMBER(4) := 7902;
BEGIN
  SELECT sal, mgr INTO salary, mgr_num FROM emp
  WHERE empno = starting_empno;
  WHILE salary < 4000 LOOP
    SELECT sal, mgr, ename INTO salary, mgr_num, last_name
    FROM emp WHERE empno = mgr_num;
  END LOOP;
  INSERT INTO temp VALUES (NULL, salary, last_name);
  COMMIT;
END;
```

The EXIT–WHEN statement lets you complete a loop if further processing is impossible or undesirable. When the EXIT statement is encountered, the condition in the WHEN clause is evaluated. If the condition yields TRUE, the loop completes and control passes to the next statement. In the following example, the loop completes when the value of `total` exceeds 25,000:

```
LOOP
  ...
  total := total + salary;
  EXIT WHEN total > 25000;  -- exit loop if condition is true
END LOOP;
```

Sequential Control

The GOTO statement lets you branch to a label unconditionally. The label, an undeclared identifier enclosed by double angle brackets, must precede an executable statement or a PL/SQL block. When executed, the GOTO statement transfers control to the labeled statement or block, as the following example shows:

```
IF rating > 90 THEN
  GOTO calc_raise;  -- branch to label
END IF;
...
<<calc_raise>>
IF job_title = 'SALESMAN' THEN  -- control resumes here
  amount := commission * 0.25;
ELSE
  amount := salary * 0.10;
END IF;
```
Modularity

Modularity lets you break an application down into manageable, well–defined logic modules. Through successive refinement, you can reduce a complex problem to a set of simple problems that have easy–to–implement solutions. PL/SQL meets this need with program units. Besides blocks and subprograms, PL/SQL provides the package, which allows you to group related program objects into larger units.

Subprograms

PL/SQL has two types of subprograms called procedures and functions, which can take parameters and be invoked (called). As the following example shows, a subprogram is like a miniature program, beginning with a header followed by an optional declarative part, an executable part, and an optional exception–handling part:

```plsql
PROCEDURE award_bonus (emp_id NUMBER) IS
    bonus        REAL;
    comm_missing EXCEPTION;
BEGIN
    SELECT comm * 0.15 INTO bonus FROM emp WHERE empno = emp_id;
    IF bonus IS NULL THEN
        RAISE comm_missing;
    ELSE
        UPDATE payroll SET pay = pay + bonus WHERE empno = emp_id;
    END IF;
EXCEPTION
    WHEN comm_missing THEN ...
END award_bonus;
```

When called, this procedure accepts an employee number. It uses the number to select the employee’s commission from a database table and, at the same time, compute a 15% bonus. Then, it checks the bonus amount. If the bonus is null, an exception is raised; otherwise, the employee’s payroll record is updated.

Packages

PL/SQL lets you bundle logically related types, program objects, and subprograms into a package. Each package is easy to understand and the interfaces between packages are simple, clear, and well defined. This aids application development.

Packages usually have two parts: a specification and a body. The specification is the interface to your applications; it declares the types, constants, variables, exceptions, cursors, and subprograms available for use. The body defines cursors and subprograms and so implements the specification.
In the following example, you package two employment procedures:

```sql
CREATE PACKAGE emp_actions AS -- package specification
    PROCEDURE hire_employee (empno NUMBER, ename CHAR, ...);
    PROCEDURE fire_employee (emp_id NUMBER);
END emp_actions;

CREATE PACKAGE BODY emp_actions AS -- package body
    PROCEDURE hire_employee (empno NUMBER, ename CHAR, ...) IS
        BEGIN
            INSERT INTO emp VALUES (empno, ename, ...);
        END hire_employee;
    PROCEDURE fire_employee (emp_id NUMBER) IS
        BEGIN
            DELETE FROM emp WHERE empno = emp_id;
        END fire_employee;
END emp_actions;
```

Only the declarations in the package specification are visible and accessible to applications. Implementation details in the package body are hidden and inaccessible.

Packages can be compiled and stored in an Oracle database, where their contents can be shared by many applications. When you call a packaged subprogram for the first time, the whole package is loaded into memory. So, subsequent calls to related subprograms in the package require no disk I/O. Thus, packages can enhance productivity and improve performance.

**Information Hiding**

With information hiding, you see only the details that are relevant at a given level of algorithm and data structure design. Information hiding keeps high-level design decisions separate from low-level design details, which are more likely to change.

**Algorithms**

You implement information hiding for algorithms through *top-down design*. Once you define the purpose and interface specifications of a low-level procedure, you can ignore the implementation details. They are hidden at higher levels. For example, the implementation of a procedure named `raise_salary` is hidden. All you need to know is that the procedure will increase a specific employee salary by a given amount. Any changes to the definition of `raise_salary` are transparent to calling applications.

**Data Structures**

You implement information hiding for data structures though *data encapsulation*. By developing a set of utility subprograms for a data structure, you insulate it from users and other developers. That way, other developers know how to use the subprograms that operate on the data structure but not how the structure is represented.
With PL/SQL packages, you can specify whether types, program objects, and subprograms are public or private. Thus, packages enforce data encapsulation by letting you put type declarations in a black box. A private type definition is hidden and inaccessible. Only the package, not your application, is affected if the definition changes. This simplifies maintenance and enhancement.

**Error Handling**

PL/SQL makes it easy to detect and process predefined and user–defined error conditions called *exceptions*. When an error occurs, an exception is *raised*. That is, normal execution stops and control transfers to the exception–handling part of your PL/SQL block or subprogram. To handle raised exceptions, you write separate routines called *exception handlers*.

Predefined exceptions are raised implicitly by the runtime system. For example, if you try to divide a number by zero, PL/SQL raises the predefined exception ZERO_DIVIDE automatically. You must raise user–defined exceptions explicitly with the RAISE statement.

You can define exceptions of your own in the declarative part of any PL/SQL block or subprogram. In the executable part, you check for the condition that needs special attention. If you find that the condition exists, you execute a RAISE statement. In the example below, you compute the bonus earned by a salesperson. The bonus is based on salary and commission. So, if the commission is null, you raise the exception *comm_missing*.

```
DECLARE
  salary       NUMBER(7,2);
  commission   NUMBER(7,2);
  comm_missing EXCEPTION;  -- declare exception
BEGIN
  SELECT sal, comm INTO salary, commission FROM emp
    WHERE empno = :emp_id;
  IF commission IS NULL THEN
    RAISE comm_missing;  -- raise exception
  ELSE
    :bonus := (salary * 0.05) + (commission * 0.15);
  END IF;
EXCEPTION  -- begin exception handlers
  WHEN comm_missing THEN
    -- process error
END;
```

The variables `emp_id` and `bonus` are declared and assigned values in a host environment. For more information about host variables, see “Oracle Precompiler Environment” on page 8 – 5.
Architecture

The PL/SQL runtime system is a technology, not an independent product. Think of this technology as an engine that executes PL/SQL blocks and subprograms. The engine can be installed in an Oracle Server or in an application development tool such as Oracle Forms or Oracle Reports. So, PL/SQL can reside in two environments:

- the Oracle Server
- Oracle tools

These two environments are independent. PL/SQL might be available in the Oracle Server but unavailable in tools, or the other way around. In either environment, the PL/SQL engine accepts as input any valid PL/SQL block or subprogram. Figure 1 – 4 shows the PL/SQL engine processing an anonymous block.

Figure 1 – 4 PL/SQL Engine

The PL/SQL engine executes procedural statements but sends SQL statements to the SQL Statement Executor in the Oracle Server.
**In the Oracle Server**

Application development tools that lack a local PL/SQL engine must rely on Oracle to process PL/SQL blocks and subprograms. When it contains the PL/SQL engine, an Oracle Server can process PL/SQL blocks and subprograms as well as single SQL statements. The Oracle Server passes the blocks and subprograms to its local PL/SQL engine.

**Anonymous Blocks**

Anonymous PL/SQL blocks can be embedded in an Oracle Precompiler or OCI program. At run time, the program, lacking a local PL/SQL engine, sends these blocks to the Oracle Server, where they are compiled and executed. Likewise, interactive tools such as SQL*Plus and Server Manager, lacking a local PL/SQL engine, must send anonymous blocks to Oracle.

**Stored Subprograms**

Named PL/SQL blocks (subprograms) can be compiled separately and stored permanently in an Oracle database, ready to be executed. A subprogram explicitly CREATEd using an Oracle tool is called a stored subprogram. Once compiled and stored in the data dictionary, it is a database object, which can be referenced by any number of applications connected to that database.

Stored subprograms defined within a package are called packaged subprograms; those defined independently are called standalone subprograms. (Subprograms defined within another subprogram or within a PL/SQL block are called local subprograms. They cannot be referenced by other applications and exist only for the convenience of the enclosing block.)

Stored subprograms offer higher productivity, better performance, memory savings, application integrity, and tighter security. For example, by designing applications around a library of stored procedures and functions, you can avoid redundant coding and increase your productivity.

You can call stored subprograms from a database trigger, another stored subprogram, an Oracle Precompiler application, an OCI application, or interactively from SQL*Plus or Server Manager. For example, you might call the standalone procedure `create_dept` from SQL*Plus as follows:

```
SQL> EXECUTE create_dept('FINANCE', 'NEW YORK');
```

Subprograms are stored in parsed, compiled form. So, when called, they are loaded and passed to the PL/SQL engine immediately. Moreover, stored subprograms take advantage of the Oracle shared memory capability. Only one copy of a subprogram need be loaded into memory for execution by multiple users.
Database Triggers

A database trigger is a stored subprogram associated with a table. You can have Oracle automatically fire the database trigger before or after an INSERT, UPDATE, or DELETE statement affects the table. One of the many uses for database triggers is to audit data modifications. For example, the following database trigger fires whenever salaries in the emp table are updated:

```
CREATE TRIGGER audit_sal
    AFTER UPDATE OF sal ON emp
    FOR EACH ROW
BEGIN
    INSERT INTO emp_audit VALUES ... 
END;
```

You can use all the SQL data manipulation statements and any procedural statement in the executable part of a database trigger.

In Oracle Tools

When it contains the PL/SQL engine, an application development tool can process PL/SQL blocks. The tool passes the blocks to its local PL/SQL engine. The engine executes all procedural statements at the application site and sends only SQL statements to Oracle. Thus, most of the work is done at the application site, not at the server site.

Furthermore, if the block contains no SQL statements, the engine executes the entire block at the application site. This is useful if your application can benefit from conditional and iterative control.

Frequently, Oracle Forms applications use SQL statements merely to test the value of field entries or to do simple computations. By using PL/SQL instead, you can avoid calls to the Oracle Server. Moreover, you can use PL/SQL functions to manipulate field entries.

Advantages of PL/SQL

PL/SQL is a completely portable, high-performance transaction processing language that offers the following advantages:

• support for SQL
• higher productivity
• better performance
• portability
• integration with Oracle
Support for SQL

SQL has become the standard database language because it is flexible, powerful, and easy to learn. A few English–like commands such as INSERT, UPDATE, and DELETE make it easy to manipulate the data stored in a relational database.

SQL is non–procedural, meaning that you can state what you want done without stating how to do it. Oracle determines the best way to carry out your request. There is no necessary connection between consecutive statements because Oracle executes SQL statements one at a time.

PL/SQL lets you use all the SQL data manipulation, cursor control, and transaction control commands, as well as all the SQL functions, operators, and pseudocolumns. So, you can manipulate Oracle data flexibly and safely.

Higher Productivity

PL/SQL adds functionality to non–procedural tools such as Oracle Forms and Oracle Reports. With PL/SQL in these tools, you can use familiar procedural constructs to build applications. For example, you can use an entire PL/SQL block in an Oracle Forms trigger. You need not use multiple trigger steps, macros, or user exits. Thus, PL/SQL increases productivity by putting better tools in your hands.

Moreover, PL/SQL is the same in all environments. As soon as you master PL/SQL with one Oracle tool, you can transfer your knowledge to other tools, and so multiply the productivity gains. For example, scripts written with one tool can be used by other tools.

Better Performance

Without PL/SQL, Oracle must process SQL statements one at a time. Each SQL statement results in another call to Oracle and higher performance overhead. In a networked environment, the overhead can become significant. Every time a SQL statement is issued, it must be sent over the network, creating more traffic.

However, with PL/SQL, an entire block of statements can be sent to Oracle at one time. This can drastically reduce communication between your application and Oracle. As Figure 1 – 5 shows, if your application is database intensive, you can use PL/SQL blocks and subprograms to group SQL statements before sending them to Oracle for execution.
Applications written in PL/SQL are portable to any operating system and platform on which Oracle runs. In other words, PL/SQL programs can run anywhere Oracle can run; you need not tailor them to each new environment. That means you can write portable program libraries, which can be reused in different environments.

Integration with Oracle

Both PL/SQL and Oracle are based on SQL. Moreover, PL/SQL supports all the SQL datatypes. Combined with the direct access that SQL provides, these shared datatypes integrate PL/SQL with the Oracle data dictionary.

The %TYPE and %ROWTYPE attributes further integrate PL/SQL with the data dictionary. For example, you can use the %TYPE attribute to declare variables, basing the declarations on the definitions of database columns. If a definition changes, the variable declaration changes accordingly at run time. This provides data independence, reduces maintenance costs, and allows programs to adapt as the database changes to meet new business needs.
Fundamentals

There are six essentials in painting. The first is called spirit; the second, rhythm; the third, thought; the fourth, scenery; the fifth, the brush; and the last is the ink.

Ching Hao

The previous chapter provided an overview of PL/SQL. This chapter focuses on the small-scale aspects of the language. Like every other programming language, PL/SQL has a character set, reserved words, punctuation, datatypes, rigid syntax, and fixed rules of usage and statement formation. You use these basic elements of PL/SQL to represent real-world objects and operations.
Character Set

You write a PL/SQL program as lines of text using a specific set of characters. The PL/SQL character set includes

- the upper and lowercase letters A .. Z, a .. z
- the numerals 0 .. 9
- tabs, spaces, and carriage returns
- the symbols ( ) + – * / < > = ! ~ ; : . ’ @ % , “ # $ ^ & _ { } ? [ ]

PL/SQL is not case sensitive, so lowercase letters are equivalent to corresponding uppercase letters except within string and character literals.

Lexical Units

A line of PL/SQL text contains groups of characters known as lexical units, which can be classified as follows:

- delimiters (simple and compound symbols)
- identifiers, which include reserved words
- literals
- comments

For example, the line

```
bonus := salary * 0.10; -- compute bonus
```

contains the following lexical units:

- identifiers bonus and salary
- compound symbol :=
- simple symbols * and ;
- numeric literal 0.10
- comment -- compute bonus

To improve readability, you can separate lexical units by spaces. In fact, you must separate adjacent identifiers by a space or punctuation. For example, the following line is illegal because the reserved words END and IF are joined:

```
IF x > y THEN high := x; ENDF; -- illegal
```
However, you cannot embed spaces in lexical units except for string literals and comments. For example, the following line is illegal because the compound symbol for assignment (:=) is split:

\[
\text{count : = count } \text{ + 1}; \quad \text{-- illegal}
\]

To show structure, you can divide lines using carriage returns and indent lines using spaces or tabs. Compare the following IF statements for readability:

\[
\begin{align*}
\text{IF } & x > y \text{ THEN } \text{ max := x; } \text{ELSE } \text{ max := y; } \text{END IF;} \\
\text{IF } & x > y \text{ THEN } \\
& \text{max := x;} \\
& \text{ELSE} \\
& \text{max := y;} \\
& \text{END IF;}
\end{align*}
\]

**Delimiters**

A delimiter is a simple or compound symbol that has a special meaning to PL/SQL. For example, you use delimiters to represent arithmetic operations such as addition and subtraction.

**Simple Symbols**

Simple symbols consist of one character; a list follows:

\[
\begin{align*}
\text{+} & \quad \text{addition operator} \\
\text{-} & \quad \text{subtraction/negation operator} \\
\text{*} & \quad \text{multiplication operator} \\
\text{/} & \quad \text{division operator} \\
\text{=} & \quad \text{relational operator} \\
\text{<} & \quad \text{relational operator} \\
\text{>} & \quad \text{relational operator} \\
\text{(} & \quad \text{expression or list delimiter} \\
\text{)} & \quad \text{expression or list delimiter} \\
; & \quad \text{statement terminator} \\
\% & \quad \text{attribute indicator} \\
, & \quad \text{item separator} \\
. & \quad \text{component selector} \\
@ & \quad \text{remote access indicator} \\
' & \quad \text{character string delimiter} \\
" & \quad \text{quoted identifier delimiter} \\
: & \quad \text{host variable indicator}
\end{align*}
\]
Compound Symbols

Compound symbols consist of two characters; a list follows:

- `**` exponentiation operator
- `<>` relational operator
- `!=` relational operator
- `~=` relational operator
- `^=` relational operator
- `<=` relational operator
- `>=` relational operator
- `:=` assignment operator
- `=>` association operator
- `..` range operator
- `||` concatenation operator
- `<<` (beginning) label delimiter
- `>>` (ending) label delimiter
- `--` single–line comment indicator
- `/*` (beginning) multi–line comment delimiter
- `*/` (ending) multi–line comment delimiter

Identifiers

You use identifiers to name PL/SQL program objects and units, which include constants, variables, exceptions, cursors, cursor variables, subprograms, and packages. Some examples of identifiers follow:

- `X`
- `t2`
- `phone#`
- `credit_limit`
- `LastName`
- `oracle$number`

An identifier consists of a letter optionally followed by more letters, numerals, dollar signs, underscores, and number signs. Other characters such as hyphens, slashes, and spaces are illegal, as the following examples show:

- `mine&yours` -- illegal ampersand
- `debit–amount` -- illegal hyphen
- `on/off` -- illegal slash
- `user id` -- illegal space
The next examples show that adjoining and trailing dollar signs, underscores, and number signs are legal:

money$tree
SN##
try_again_

You can use upper, lower, or mixed case to write identifiers. PL/SQL is not case sensitive except within string and character literals. So, if the only difference between identifiers is the case of corresponding letters, PL/SQL considers the identifiers to be the same, as the following example shows:

lastname
LastName -- same as lastname
LASTNAME -- same as lastname and LastName

The length of an identifier cannot exceed 30 characters. But, every character, including dollar signs, underscores, and number signs, is significant. For example, PL/SQL considers the following identifiers to be different:

lastname
last_name

Identifiers should be descriptive. So, use meaningful names such as credit_limit and cost_per_thousand. Avoid obscure names such as cr_lim and cpm.

Reserved Words

Some identifiers, called reserved words, have a special syntactic meaning to PL/SQL and so cannot be redefined. For example, the words BEGIN and END, which bracket the executable part of a block or subprogram, are reserved. As the next example shows, if you try to redefine a reserved word, you get a compilation error:

DECLARE
   end BOOLEAN;  -- illegal; causes compilation error

However, you can embed reserved words in an identifier, as the following example shows:

DECLARE
   end_of_game BOOLEAN;  -- legal

Often, reserved words are written in uppercase to promote readability. However, like other PL/SQL identifiers, reserved words can be written in lower or mixed case. For a list of reserved words, see Appendix E.
Predefined Identifiers

Identifiers globally declared in package STANDARD, such as the exception INVALID_NUMBER, can be redeclared. However, redeclaring predefined identifiers is error prone because your local declaration overrides the global declaration.

Quoted Identifiers

For flexibility, PL/SQL lets you enclose identifiers within double quotes. Quoted identifiers are seldom needed, but occasionally they can be useful. They can contain any sequence of printable characters including spaces but excluding double quotes. Thus, the following identifiers are legal:

"X+Y"
"last name"
"on/off switch"
"employee(s)"
"*** header info ***"

The maximum length of a quoted identifier is 30 characters not counting the double quotes.

Using PL/SQL reserved words as quoted identifiers is allowed but not recommended. It is poor programming practice to reuse reserved words.

Some PL/SQL reserved words are not reserved by SQL. For example, you can use the PL/SQL reserved word TYPE in a CREATE TABLE statement to name a database column. But, if a SQL statement in your program refers to that column, you get a compilation error, as the following example shows:

SELECT acct, type, bal INTO ... -- causes compilation error

To prevent the error, enclose the uppercase column name in double quotes, as follows:

SELECT acct, "TYPE", bal INTO ...

The column name cannot appear in lower or mixed case (unless it was defined that way in the CREATE TABLE statement). For example, the following statement is invalid:

SELECT acct, "type", bal INTO ... -- causes compilation error

Alternatively, you can create a view that renames the troublesome column, then use the view instead of the base table in SQL statements.
Literals

A literal is an explicit numeric, character, string, or Boolean value not represented by an identifier. The numeric literal 147 and the Boolean literal FALSE are examples.

Numeric Literals

Two kinds of numeric literals can be used in arithmetic expressions: integers and reals. An integer literal is an optionally signed whole number without a decimal point. Some examples follow:

0 30 6 -14 0 +32767

A real literal is an optionally signed whole or fractional number with a decimal point. Several examples follow:

6.6667 0.0 -12.0 3.14159 +8300.00 .5 25.

PL/SQL considers numbers such as 12.0 and 25. to be reals even though they have integral values.

Numeric literals cannot contain dollar signs or commas, but can be written using scientific notation. Simply suffix the number with an E (or e) followed by an optionally signed integer. A few examples follow:

2E5 1.0E-7 3.14159e0 -1E38 -9.5e-3

E stands for "times ten to the power of." As the next example shows, the number after E is the power of ten by which the number before E must be multiplied:

5E3 = 5 \times 10^3 = 5 \times 1000 = 5000

The number after E also corresponds to the number of places the decimal point shifts. In the last example, the implicit decimal point shifted three places to the right; in the next example, it shifts three places to the left:

5E-3 = 5 \times 10^{-3} = 5 \times 0.001 = 0.005

Character Literals

A character literal is an individual character enclosed by single quotes (apostrophes). Several examples follow:

'Z' 'z' '7' ',' 'Z' '('.

Character literals include all the printable characters in the PL/SQL character set: letters, numerals, spaces, and special symbols. PL/SQL is case sensitive within character literals. For example, PL/SQL considers the literals 'Z' and 'z' to be different.

Do not confuse the character literals '0' .. '9' with integer literals. Character literals cannot be used in arithmetic expressions.
String Literals

A character value can be represented by an identifier or explicitly written as a string literal, which is a sequence of zero or more characters enclosed by single quotes. Several examples follow:

‘Hello, world!’
‘XYZ Corporation’
‘10–NOV–91’
‘He said “Life is like licking honey from a thorn.”’
‘$1,000,000’

All string literals except the null string ("") have datatype CHAR.

Given that apostrophes (single quotes) delimit string literals, how do you represent an apostrophe within a string? As the next example shows, you write two single quotes, which is not the same as writing a double quote:

‘Don’t leave without saving your work.’

PL/SQL is case sensitive within string literals. For example, PL/SQL considers the following literals to be different:

‘baker’
‘Baker’

Boolean Literals

Boolean literals are the predefined values TRUE and FALSE and the non–value NULL, which stands for a missing, unknown, or inapplicable value. Remember, Boolean literals are values, not strings. For example, TRUE is no less a value than the number 25.

Comments

The PL/SQL compiler ignores comments, but you should not. Adding comments to your program promotes readability and aids understanding. Generally, you use comments to describe the purpose and use of each code segment. PL/SQL supports two comment styles: single line and multi–line.

Single–Line

Single–line comments begin with a double hyphen (––) anywhere on a line and extend to the end of the line. A few examples follow:

-- begin processing
SELECT sal INTO salary FROM emp -- get current salary
    WHERE empno = emp_id;
bias := salary * 0.15;  -- compute bonus amount

Notice that comments can appear within a statement at the end of a line.

While testing or debugging a program, you might want to disable a line of code. The following example shows how you can “comment–out” the line:

-- DELETE FROM emp WHERE comm IS NULL;
Multi–line

Multi–line comments begin with a slash–asterisk (/*), end with an asterisk–slash (*/), and can span multiple lines. An example follows:

```plsql
/* compute a 15% bonus for top–rated employees */
IF rating > 90 THEN
    bonus := salary * 0.15;
END IF;
```

You can use multi–line comment delimiters to comment–out whole sections of code, as the following example shows:

```plsql
/* OPEN c1;
   LOOP
      FETCH c1 INTO my_empno, my_ename, my_sal;
      EXIT WHEN c1%NOTFOUND;
      ...
   END LOOP;
   CLOSE c1; */
```

Restrictions

You cannot nest comments. Also, you cannot use single–line comments in a PL/SQL block that will be processed dynamically by an Oracle Precompiler program because end–of–line characters are ignored. As a result, single–line comments extend to the end of the block, not just to the end of a line. So, use multi–line comments instead.

Datatypes

Every constant and variable has a datatype, which specifies a storage format, constraints, and valid range of values. PL/SQL provides a variety of predefined scalar and composite datatypes. A scalar type has no internal components. A composite type has internal components that can be manipulated individually. A reference type contains values, called pointers, that designate other program objects.

Figure 2 – 1 shows the predefined datatypes available for your use. An additional scalar type, MLSLABEL, is available with Trusted Oracle, a specially secured version of Oracle. The scalar types fall into four families, which store number, character, date/time, or Boolean data, respectively.
This section discusses the scalar types; the composite types are discussed later in this chapter; the reference type is discussed in “Using Cursor Variables” on page 4 – 17.

**BINARY_INTEGER**

You use the BINARY_INTEGER datatype to store signed integers. The magnitude range of a binary integer value is \(-2^{147483647} .. 2^{147483647}\). PL/SQL represents BINARY_INTEGER values as signed binary numbers, which, unlike NUMBER values, can be used in calculations without conversion.

**BINARY_INTEGER Subtypes**

A subtype associates a base type with a constraint and so defines a subset of values. For convenience, PL/SQL predefines the following BINARY_INTEGER subtypes:

- **NATURAL** (0 .. 2147483647)
- **POSITIVE** (1 .. 2147483647)

You can use the NATURAL or POSITIVE subtype when you want to restrict a variable to non-negative integer values.

---

**Figure 2 – 1 Predefined Datatypes**

This section discusses the scalar types; the composite types are discussed later in this chapter; the reference type is discussed in “Using Cursor Variables” on page 4 – 17.
**NUMBER**

You use the NUMBER datatype to store fixed or floating-point numbers of virtually any size. You can specify *precision*, which is the total number of digits, and *scale*, which determines where rounding occurs. The syntax follows:

```sql
NUMBER[(precision, scale)]
```

You cannot use constants or variables to specify precision and scale; you must use integer literals.

The maximum precision of a NUMBER value is 38 decimal digits; the magnitude range is \(1.0 \times 10^{-129} \ldots 9.99 \times 10^{125}\). If you do not specify the precision, it defaults to the maximum value supported by your system.

Scale can range from \(-84\) to \(127\). For instance, a scale of \(2\) rounds to the nearest hundredth (3.456 becomes 3.46). Scale can be negative, which causes rounding to the left of the decimal point. For example, a scale of \(-3\) rounds to the nearest thousand (3456 becomes 3000). A scale of zero rounds to the nearest whole number. If you do not specify the scale, it defaults to zero.

**NUMBER Subtypes**

The NUMBER subtypes below have the same range of values as their base type. For example, DECIMAL is just another name for NUMBER.

- DEC
- DECIMAL
- DOUBLE PRECISION
- INTEGER
- INT
- NUMERIC
- REAL
- SMALLINT

FLOAT is another subtype of NUMBER. However, you cannot specify a scale for FLOAT variables; you can only specify a binary precision. The maximum precision of a FLOAT value is 126 binary digits, which is roughly equivalent to 38 decimal digits.

You can use these subtypes for compatibility with ANSI/ISO and IBM types or when you want an identifier more descriptive than NUMBER.
CHAR

You use the CHAR datatype to store fixed–length (blank–padded if necessary) character data. How the data is represented internally depends on the database character set, which might be 7–bit ASCII or EBCDIC Code Page 500, for example.

The CHAR datatype takes an optional parameter that lets you specify a maximum length up to 32767 bytes. The syntax follows:

```
CHAR[<maximum_length>]
```

You cannot use a constant or variable to specify the maximum length; you must use an integer literal. If you do not specify the maximum length, it defaults to 1.

Remember, you specify the maximum length of a CHAR(n) variable in bytes, not characters. So, if a CHAR(n) variable stores multi–byte characters, its maximum length is less than n characters.

Although the maximum length of a CHAR(n) variable is 32767 bytes, the maximum width of a CHAR database column is 255 bytes. Therefore, you cannot insert values longer than 255 bytes into a CHAR column. You can insert any CHAR(n) value into a LONG database column because the maximum width of a LONG column is 2147483647 bytes or 2 gigabytes. However, you cannot select a value longer than 32767 bytes from a LONG column into a CHAR(n) variable.

CHAR Subtype

The CHAR subtype CHARACTER has the same range of values as its base type. That is, CHARACTER is just another name for CHAR. You can use this subtype for compatibility with ANSI/ISO and IBM types or when you want an identifier more descriptive than CHAR.

VARCHAR2

You use the VARCHAR2 datatype to store variable–length character data. How the data is represented internally depends on the database character set.

The VARCHAR2 datatype takes a required parameter that specifies a maximum length up to 32767 bytes. The syntax follows:

```
VARCHAR2(<maximum_length>)
```

You cannot use a constant or variable to specify the maximum length; you must use an integer literal.

Remember, you specify the maximum length of a VARCHAR2(n) variable in bytes, not characters. So, if a VARCHAR2(n) variable stores multi–byte characters, its maximum length is less than n characters.
Although the maximum length of a VARCHAR2\((n)\) variable is 32767 bytes, the maximum width of a VARCHAR2 database column is 2000 bytes. Therefore, you cannot insert values longer than 2000 bytes into a VARCHAR2 column. You can insert any VARCHAR2\((n)\) value into a LONG database column because the maximum width of a LONG column is 2147483647 bytes. However, you cannot select a value longer than 32767 bytes from a LONG column into a VARCHAR2\((n)\) variable.

Some important semantic differences between the CHAR and VARCHAR2 base types are described in Appendix C.

**VARCHAR2 Subtypes**

The VARCHAR2 subtypes below have the same range of values as their base type. For example, VARCHAR is just another name for VARCHAR2.

- **STRING**
- **VARCHAR**

You can use these subtypes for compatibility with ANSI/ISO and IBM types. However, the VARCHAR datatype might change to accommodate emerging SQL standards. So, it is a good idea to use VARCHAR2 rather than VARCHAR.

**LONG**

You use the LONG datatype to store variable-length character strings. The LONG datatype is like the VARCHAR2 datatype, except that the maximum length of a LONG value is 32760 bytes.

You can insert any LONG value into a LONG database column because the maximum width of a LONG column is 2147483647 bytes. However, you cannot select a value longer than 32760 bytes from a LONG column into a LONG variable.

LONG columns can store text, arrays of characters, or even short documents. You can reference LONG columns in UPDATE, INSERT, and (most) SELECT statements, but not in expressions, SQL function calls, or certain SQL clauses such as WHERE, GROUP BY, and CONNECT BY. For more information, see *Oracle7 Server SQL Reference*.

**RAW**

You use the RAW datatype to store binary data or byte strings. For example, a RAW variable might store a sequence of graphics characters or a digitized picture. Raw data is like character data, except that PL/SQL does not interpret raw data. Likewise, Oracle does no character set conversions (from 7–bit ASCII to EBCDIC Code Page 500, for example) when you transmit raw data from one system to another.
The RAW datatype takes a required parameter that lets you specify a maximum length up to 32767 bytes. The syntax follows:

\texttt{RAW(maximum\_length)}

You cannot use a constant or variable to specify the maximum length; you must use an integer literal.

Although the maximum length of a RAW variable is 32767 bytes, the maximum width of a RAW database column is 255 bytes. Therefore, you cannot insert values longer than 255 bytes into a RAW column. You can insert any RAW value into a LONG RAW database column because the maximum width of a LONG RAW column is 2147483647 bytes. However, you cannot select a value longer than 32767 bytes from a LONG RAW column into a RAW variable.

**LONG RAW**

You use the LONG RAW datatype to store binary data or byte strings. LONG RAW data is like LONG data, except that LONG RAW data is not interpreted by PL/SQL. The maximum length of a LONG RAW value is 32760 bytes.

You can insert any LONG RAW value into a LONG RAW database column because the maximum width of a LONG RAW column is 2147483647 bytes. However, you cannot select a value longer than 32760 bytes from a LONG RAW column into a LONG RAW variable.

**ROWID**

Internally, every Oracle database table has a ROWID pseudocolumn, which stores binary values called rowids. Rowids uniquely identify rows and provide the fastest way to access particular rows. You use the ROWID datatype to store rowids in a readable format. The maximum length of a ROWID variable is 256 bytes.

When you select or fetch a rowid into a ROWID variable, you can use the function ROWIDTOCHAR, which converts the binary value to an 18-byte character string and returns it in the format

\texttt{BBBBBBB.BRRR.FFFF}

where BBBB BBBBB is the block in the database file, RRRR is the row in the block (the first row is 0), and FFFF is the database file. These numbers are hexadecimal. For example, the rowid

\texttt{000000E.000A.0007}

points to the 11th row in the 15th block in the 7th database file.

Typically, ROWID variables are compared to the ROWID pseudocolumn in the WHERE clause of an UPDATE or DELETE statement to identify the latest row fetched from a cursor. For an example, see “Fetching Across Commits” on page 4 – 43.
**BOOLEAN**

You use the BOOLEAN datatype to store the values TRUE and FALSE and the non-value NULL. Recall that NULL stands for a missing, unknown, or inapplicable value.

The BOOLEAN datatype takes no parameters. Only the values TRUE and FALSE and the non-value NULL can be assigned to a BOOLEAN variable. You cannot insert the values TRUE and FALSE into a database column. Furthermore, you cannot select or fetch column values into a BOOLEAN variable.

**DATE**

You use the DATE datatype to store fixed-length date values. The DATE datatype takes no parameters. Valid dates for DATE variables include January 1, 4712 BC to December 31, 4712 AD.

When stored in a database column, date values include the time of day in seconds since midnight. The date portion defaults to the first day of the current month; the time portion defaults to midnight.

**MLSLABEL**

With Trusted Oracle, you use the MLSLABEL datatype to store variable-length, binary operating system labels. Trusted Oracle uses labels to control access to data. For more information, see *Trusted Oracle Server Administrator's Guide, Release 7.1*.

You can use the MLSLABEL datatype to define a database column. Also, you can use the %TYPE and %ROWTYPE attributes to reference the column. However, with standard Oracle, such columns can store only nulls.

With Trusted Oracle, you can insert any valid operating system label into a column of type MLSLABEL. If the label is in text format, Trusted Oracle converts it to a binary value automatically. The text string can be up to 255 bytes long. However, the internal length of an MLSLABEL value is between 2 and 5 bytes.

With Trusted Oracle, you can also select values from a MLSLABEL column into a character variable. Trusted Oracle converts the internal binary value to a VARCHAR2 value automatically.
Datatype Conversion

Sometimes it is necessary to convert a value from one datatype to another. For example, if you want to examine a rowid, you must convert it to a character string. PL/SQL supports both explicit and implicit (automatic) datatype conversion.

Explicit Conversion

To specify conversions explicitly, you use built-in functions that convert values from one datatype to another. Table 2–1 shows which function to use in a given situation. For example, to convert a CHAR value to a NUMBER value, you use the function TO_NUMBER. For more information about these functions, see Oracle7 Server SQL Reference.

<table>

</tr>
</tbody>
</table>

Table 2–1 Conversion Functions

Implicit Conversion

When it makes sense, PL/SQL can convert the datatype of a value implicitly. This allows you to use literals, variables, and parameters of one type where another type is expected. In the example below, the CHAR variables start_time and finish_time hold string values representing the number of seconds past midnight. The difference between those values must be assigned to the NUMBER variable elapsed_time. So, PL/SQL converts the CHAR values to NUMBER values automatically.

```
DECLARE
    start_time   CHAR(5);
    finish_time  CHAR(5);
    elapsed_time NUMBER(5);
BEGIN
    /* Get system time as seconds past midnight. */
    SELECT TO_CHAR(SYSDATE,'SSSSS') INTO start_time FROM sys.dual;
    /* do something */
    SELECT TO_CHAR(SYSDATE,'SSSSS') INTO finish_time FROM sys.dual;
    /* Compute elapsed time in seconds. */
    elapsed_time := finish_time - start_time;
    INSERT INTO results VALUES (elapsed_time, ...);
END;
```
Before assigning a selected column value to a variable, PL/SQL will, if necessary, convert the value from the datatype of the source column to the datatype of the variable. This happens, for example, when you select a DATE column value into a VARCHAR2 variable. Likewise, before assigning the value of a variable to a database column, PL/SQL will, if necessary, convert the value from the datatype of the variable to the datatype of the target column.

If PL/SQL cannot determine which implicit conversion is needed, you get a compilation error. In such cases, you must use a datatype conversion function. Table 2 – 2 shows which implicit conversions PL/SQL can do.

<table>

</tr>
</tbody>
</table>

Table 2 – 2 Implicit Conversions

It is your responsibility to ensure that values are convertible. For instance, PL/SQL can convert the CHAR value ‘02–JUN–92’ to a DATE value, but PL/SQL cannot convert the CHAR value ‘YESTERDAY’ to a DATE value. Similarly, PL/SQL cannot convert a VARCHAR2 value containing alphabetic characters to a NUMBER value.

**Implicit versus Explicit Conversion**

Generally, it is poor programming practice to rely on implicit datatype conversions because they can hamper performance and might change from one software release to the next. Also, implicit conversions are context sensitive and therefore not always predictable. Instead, use datatype conversion functions. That way, your applications will be more reliable and easier to maintain.

**DATE Values**

When you select a DATE column value into a CHAR or VARCHAR2 variable, PL/SQL must convert the internal binary value to a character value. So, PL/SQL calls the function TO_CHAR, which returns a character string in the default date format. To get other information such as the time or Julian date, you must call TO_CHAR with a format mask.
A conversion is also necessary when you insert a CHAR or VARCHAR2 value into a DATE column. So, PL/SQL calls the function TO_DATE, which expects the default date format. To insert dates in other formats, you must call TO_DATE with a format mask.

**RAW and LONG RAW Values**

When you select a RAW or LONG RAW column value into a CHAR or VARCHAR2 variable, PL/SQL must convert the internal binary value to a character value. In this case, PL/SQL returns each binary byte of RAW or LONG RAW data as a pair of characters. Each character represents the hexadecimal equivalent of a nibble (half a byte). For example, PL/SQL returns the binary byte 11111111 as the pair of characters 'FF'. The function RAWTOHEX does the same conversion.

A conversion is also necessary when you insert a CHAR or VARCHAR2 value into a RAW or LONG RAW column. Each pair of characters in the variable must represent the hexadecimal equivalent of a binary byte. If either character does not represent the hexadecimal equivalent of a nibble, PL/SQL raises an exception.

### Declarations

Your program stores values in variables and constants. As the program executes, the values of variables can change, but the values of constants cannot.

You can declare variables and constants in the declarative part of any PL/SQL block, subprogram, or package. Declarations allocate storage space for a value, specify its datatype, and name the storage location so that you can reference it. A couple of examples follow:

```sql
birthdate DATE;
emp_count SMALLINT := 0;
```

The first declaration names a variable of type DATE. The second declaration names a variable of type SMALLINT and uses the assignment operator (:=) to assign an initial value of zero to the variable.

The next examples show that the expression following the assignment operator can be arbitrarily complex and can refer to previously initialized variables:

```sql
pi    REAL := 3.14159;
radius REAL := 1;
area   REAL := pi * radius**2;
```
By default, variables are initialized to NULL. For example, the following declarations are equivalent:

```sql
birthdate DATE;
birthdate DATE := NULL;
```

In constant declarations, the reserved word CONSTANT must precede the type specifier, as the following example shows:

```sql
credit_limit CONSTANT REAL := 5000.00;
```

This declaration names a constant of type REAL and assigns an initial (also final) value of 5000 to the constant. A constant must be initialized in its declaration; otherwise, you get a compilation error.

### Using DEFAULT

If you prefer, you can use the reserved word DEFAULT instead of the assignment operator to initialize variables and constants. For example, the declarations

```sql
tax_year SMALLINT := 92;
valid BOOLEAN := FALSE;
```

can be rewritten as follows:

```sql
tax_year SMALLINT DEFAULT 92;
valid BOOLEAN DEFAULT FALSE;
```

You can also use DEFAULT to initialize subprogram parameters, cursor parameters, and fields in a user–defined record.

### Using NOT NULL

Besides assigning an initial value, declarations can impose the NOT NULL constraint, as the following example shows:

```sql
acct_id INTEGER(4) NOT NULL := 9999;
```

You cannot assign nulls to a variable defined as NOT NULL. If you try, PL/SQL raises the predefined exception VALUE_ERROR. The NOT NULL constraint must be followed by an initialization clause; otherwise, you get a compilation error. For example, the following declaration is illegal:

```sql
acct_id INTEGER(5) NOT NULL;  -- illegal; not initialized
```

### Using %TYPE

The %TYPE attribute provides the datatype of a variable or database column. In the following example, %TYPE provides the datatype of a variable:

```sql
credit REAL(7,2);
debit credit%TYPE;
```

Variables declared using %TYPE are treated like those declared using a datatype specifier. For example, given the previous declarations, PL/SQL treats `debit` like a REAL(7,2) variable.
The next example shows that a %TYPE declaration can include an initialization clause:

```plsql
balance         NUMBER(7,2);
minimum_balance balance%TYPE := 10.00;
```

The %TYPE attribute is particularly useful when declaring variables that refer to database columns. You can reference a table and column, or you can reference an owner, table, and column, as in

```plsql
my_dname scott.dept.dname%TYPE;
```

Using %TYPE to declare `my_dname` has two advantages. First, you need not know the exact datatype of `dname`. Second, if the database definition of `dname` changes, the datatype of `my_dname` changes accordingly at run time.

Note, however, that a NOT NULL column constraint does not apply to variables declared using %TYPE. In the next example, even though the database column `empno` is defined as NOT NULL, you can assign a null to the variable `my_empno`:

```plsql
DECLARE
  my_empno emp.empno%TYPE;
  ...
BEGIN
  my_empno := NULL;  -- this works
END;
```

### Using %ROWTYPE

The %ROWTYPE attribute provides a record type that represents a row in a table (or view). The record can store an entire row of data selected from the table or fetched from a cursor or cursor variable. In the example below, you declare two records. The first record stores a row selected from the `emp` table. The second record stores a row fetched from the `c1` cursor.

```plsql
DECLARE
  emp_rec emp%ROWTYPE;
  CURSOR c1 IS SELECT deptno, dname, loc FROM dept;
  dept_rec c1%ROWTYPE;
```

Columns in a row and corresponding fields in a record have the same names and datatypes. In the following example, you select column values into a record named `emp_rec`:

```plsql
DECLARE
  emp_rec emp%ROWTYPE;
  ...
BEGIN
  SELECT * INTO emp_rec FROM emp WHERE ...
END;
```
The column values returned by the SELECT statement are stored in fields. To reference a field, you use dot notation. For example, you might reference the `deptno` field as follows:

```plaintext
IF emp_rec.deptno = 20 THEN ...
```

Also, you can assign the value of an expression to a specific field, as the following examples show:

```plaintext
emp_rec.ename := 'JOHNSON';
emp_rec.sal := emp_rec.sal * 1.15;
```

**Aggregate Assignment**

A `%ROWTYPE` declaration cannot include an initialization clause. However, there are two ways to assign values to all fields in a record at once. First, PL/SQL allows aggregate assignment between entire records if their declarations refer to the same table or cursor. For example, the following assignment is legal:

```plaintext
DECLARE
  dept_rec1 dept%ROWTYPE;
  dept_rec2 dept%ROWTYPE;
  CURSOR c1 IS SELECT deptno, dname, loc FROM dept;
  dept_rec3 c1%ROWTYPE;
BEGIN
  dept_rec1 := dept_rec2;
END;
```

However, because `dept_rec2` is based on a table and `dept_rec3` is based on a cursor, the following assignment is illegal:

```plaintext
depth_rec2 := dept_rec3; -- illegal
```

Second, you can assign a list of column values to a record by using the SELECT or FETCH statement, as the example below shows. The column names must appear in the order in which they were defined by the CREATE TABLE or CREATE VIEW statement.

```plaintext
DECLARE
  dept_rec dept%ROWTYPE;
  ...
BEGIN
  SELECT deptno, dname, loc INTO dept_rec FROM dept
  WHERE deptno = 30;
END;
```

However, you cannot assign a list of column values to a record by using an assignment statement. So, the following syntax is illegal:

```plaintext
record_name := (value1, value2, value3, ...); -- illegal
```

Although you can retrieve entire records, you cannot insert or update them. For example, the following statement is illegal:

```plaintext
INSERT INTO dept VALUES (dept_rec); -- illegal
```
Using Aliases

Select–list items fetched from a cursor associated with %ROWTYPE must have simple names or, if they are expressions, must have aliases. In the following example, you use an alias called wages:

```sql
-- available online in file EXAMP4
DECLARE
    CURSOR my_cursor IS SELECT sal + NVL(comm, 0) wages, ename FROM emp;
    my_rec my_cursor%ROWTYPE;
BEGIN
    OPEN my_cursor;
    LOOP
        FETCH my_cursor INTO my_rec;
        EXIT WHEN my_cursor%NOTFOUND;
        IF my_rec.wages > 2000 THEN
            INSERT INTO temp VALUES (NULL, my_rec.wages, my_rec.ename);
        END IF;
    END LOOP;
    CLOSE my_cursor;
END;
```

For more information about database column aliases, see *Oracle7 Server SQL Reference*.

Restrictions

PL/SQL does not allow forward references. You must declare a variable or constant before referencing it in other statements, including other declarative statements. For example, the following declaration of maxi is illegal:

```sql
maxi INTEGER := 2 * mini;  -- illegal
mini INTEGER := 15;
```

However, PL/SQL does allow the forward declaration of subprograms. For more information, see “Forward Declarations” on page 6–8.

Some languages allow you to declare a list of variables that have the same datatype. PL/SQL does not allow this. For example, the following declaration is illegal:

```sql
i, j, k SMALLINT;  -- illegal
```

The legal version follows:

```sql
i SMALLINT;
j SMALLINT;
k SMALLINT;
```
Naming Conventions

The same naming conventions apply to all PL/SQL program objects and units including constants, variables, cursors, cursor variables, exceptions, procedures, functions, and packages. Names can be simple, qualified, remote, or both qualified and remote. For example, you might use the procedure name `raise_salary` in any of the following ways:

```plaintext
raise_salary(...);                      -- simple
emp_actions.raise_salary(...);          -- qualified
raise_salary@newyork(...);              -- remote
emp_actions.raise_salary@newyork(...);  -- qualified and remote
```

In the first case, you simply use the procedure name. In the second case, you must qualify the name using dot notation because the procedure is stored in a package called `emp_actions`. In the third case, you reference the database link `newyork` because the (standalone) procedure is stored in a remote database. In the fourth case, you qualify the procedure name and reference a database link.

Synonyms

You can create synonyms to provide location transparency for remote database objects such as tables, sequences, views, standalone subprograms, and packages. However, you cannot create synonyms for objects declared within subprograms or packages. That includes constants, variables, cursors, cursor variables, exceptions, and packaged procedures.

Scoping

Within the same scope, all declared identifiers must be unique. So, even if their datatypes differ, variables and parameters cannot share the same name. For example, two of the following declarations are illegal:

```sql
DECLARE
  valid_id BOOLEAN;
  valid_id VARCHAR2(5);  -- illegal duplicate identifier
FUNCTION ... (valid_id IN INTEGER) RETURN NUMBER IS
BEGIN ... END;    -- illegal triplicate identifier
```

For the scoping rules that apply to identifiers, see “Scope and Visibility” on page 2 – 25.

Case Sensitivity

Like other identifiers, the names of constants, variables, and parameters are not case sensitive. For instance, PL/SQL considers the following names to be the same:

```sql
DECLARE
  zip_code INTEGER;
  Zip_Code INTEGER;  -- same as zip_code
  ZIP_CODE INTEGER;  -- same as zip_code and Zip_Code
```
Name Precedence

In potentially ambiguous SQL statements, the names of local variables and formal parameters take precedence over the names of database tables. For example, the following UPDATE statement fails because PL/SQL assumes that `emp` refers to the loop counter:

```sql
FOR emp IN 1..5 LOOP
    UPDATE emp SET bonus = 500 WHERE ...
END LOOP;
```

Likewise, the following SELECT statement fails because PL/SQL assumes that `emp` refers to the formal parameter:

```sql
PROCEDURE calc_bonus (emp NUMBER, bonus OUT REAL) IS
    avg_sal REAL;
BEGIN
    SELECT AVG(sal) INTO avg_sal FROM emp WHERE ...
END;
```

In such cases, you can prefix the table name with a username, as follows, but it is better programming practice to rename the variable or formal parameter:

```sql
PROCEDURE calc_bonus (emp NUMBER, bonus OUT REAL) IS
    avg_sal REAL;
BEGIN
    SELECT AVG(sal) INTO avg_sal FROM scott.emp WHERE ...
END;
```

Unlike the names of tables, the names of columns take precedence over the names of local variables and formal parameters. For example, the following DELETE statement removes all employees from the `emp` table, not just KING, because Oracle assumes that both `enames` in the WHERE clause refer to the database column:

```sql
DECLARE
    ename VARCHAR2(10) := 'KING';
BEGIN
    DELETE FROM emp WHERE ename = ename;
END;
```

In such cases, to avoid ambiguity, prefix the names of local variables and formal parameters with `my_`, as follows:

```sql
DECLARE
    my_ename VARCHAR2(10);
```

Or, use a block label to qualify references, as in

```sql
<<main>>
DECLARE
    name VARCHAR2(10) := 'KING';
BEGIN
    DELETE FROM emp WHERE ename = main.ename;
```
The next example shows that you can use a subprogram name to qualify references to local variables and formal parameters:

```sql
FUNCTION bonus (empno IN NUMBER, deptno IN NUMBER) RETURN REAL IS
job VARCHAR2(14);
BEGIN
...
SELECT ... WHERE deptno = bonus.deptno AND job = bonus.job;
    -- refers to formal parameter and local variable
```

**Scope and Visibility**

References to an identifier are resolved according to its scope and visibility. The *scope* of an identifier is that region of a program unit (block, subprogram, or package) from which you can reference the identifier. An identifier is *visible* only in the regions from which you can reference the identifier using an unqualified name. Figure 2–2 shows the scope and visibility of a variable named `x`, which is declared in an enclosing block, then redeclared in a sub–block.

![Figure 2–2 Scope and Visibility](image-url)
Identifiers declared in a PL/SQL block are considered local to that block and global to all its sub–blocks. If a global identifier is redeclared in a sub–block, both identifiers remain in scope. Within the sub–block, however, only the local identifier is visible because you must use a qualified name to reference the global identifier.

Although you cannot declare an identifier twice in the same block, you can declare the same identifier in two different blocks. The two objects represented by the identifier are distinct, and any change in one does not affect the other.

However, a block cannot reference identifiers declared in other blocks nested at the same level because those identifiers are neither local nor global to the block. The following example illustrates the scope rules:

```
DECLARE
  a CHAR;
  b REAL;
BEGIN
  -- identifiers available here: a (CHAR), b
  DECLARE
    a INTEGER;
    c REAL;
  BEGIN
    -- identifiers available here: a (INTEGER), b, c
  END;
  DECLARE
    d REAL;
  BEGIN
    -- identifiers available here: a (CHAR), b, d
  END;
  -- identifiers available here: a (CHAR), b
END;
```

Recall that global identifiers can be redeclared in a sub–block, in which case the local declaration prevails and the sub–block cannot reference the global identifier unless you use a qualified name. The qualifier can be the label of an enclosing block, as the following example shows:

```
<<outer>>
DECLARE
  birthdate DATE;
BEGIN
  DECLARE
    birthdate DATE;
  BEGIN
    ...
    IF birthdate = outer.birthdate THEN ... 
```
As the next example shows, the qualifier can also be the name of an enclosing subprogram:

```plaintext
PROCEDURE check_credit (...) IS
   rating NUMBER;
   ...
   FUNCTION valid (...) RETURN BOOLEAN IS
      rating NUMBER;
   BEGIN
      ...
      IF check_credit.rating < 3 THEN
         ...
      END IF valid;
   BEGIN
      ...
   END check_credit;
```

However, within the same scope, a label and a subprogram cannot have the same name.

---

**Assignments**

Variables and constants are initialized every time a block or subprogram is entered. By default, variables are initialized to NULL. So, unless you expressly initialize a variable, its value is undefined, as the following example shows:

```plaintext
DECLARE
   count INTEGER;
   ...
BEGIN
   count := count + 1;  -- assigns a null to count
```

Therefore, never reference a variable before you assign it a value.

You can use assignment statements to assign values to a variable. For example, the following statement assigns a new value to the variable `bonus`, overwriting its old value:

```plaintext
bonus := salary * 0.15;
```

The expression following the assignment operator can be arbitrarily complex, but it must yield a datatype that is the same as or convertible to the datatype of the variable.
Boolean Values

Only the values TRUE and FALSE and the non-value NULL can be assigned to a Boolean variable. For example, given the declaration

```
DECLARE
  done BOOLEAN;
```

the following statements are legal:

```
BEGIN
  done := FALSE;
  WHILE NOT done LOOP
    ...
  END LOOP;
END;
```

When applied to PL/SQL expressions, the relational operators return a Boolean value. So, the following assignment is legal:

```
done := (count > 500);
```

Database Values

Alternatively, you can use the SELECT (or FETCH) statement to have Oracle assign values to a variable. For each item in the SELECT list, there must be a corresponding variable in the INTO list. And, they must have compatible datatypes. An example follows:

```
SELECT ename, sal + comm INTO last_name, wages FROM emp
  WHERE empno = emp_id;
```

However, you cannot select column values into a Boolean variable.

Expressions and Comparisons

Expressions are constructed using operands and operators. An operand is a variable, constant, literal, or function call that contributes a value to an expression. An example of a simple arithmetic expression follows:

```
-\(X / 2\)
```

Unary operators such as the negation operator (\(-\)) operate on one operand; binary operators such as the division operator (\(/\)) operate on two operands. PL/SQL has no ternary operators.

The simplest expressions consist of a single variable, which yields a value directly. PL/SQL evaluates (finds the current value of) an expression by combining the values of the operands in ways specified by the operators. This always yields a single value and datatype. PL/SQL determines the datatype by examining the expression and the context in which it appears.
The operations within an expression are done in a particular order depending on their precedence (priority). Table 2–3 shows the default order of operations from first to last (top to bottom).

<table>
<thead>
<tr>
<th>Operator</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>**, NOT</td>
<td>exponentiation, logical negation</td>
</tr>
<tr>
<td>+, –</td>
<td>identity, negation</td>
</tr>
<tr>
<td>*, /</td>
<td>multiplication, division</td>
</tr>
<tr>
<td>+, –,</td>
<td></td>
</tr>
<tr>
<td>=, !=, &lt;, &gt;, &lt;=, &gt;=, IS NULL, LIKE, BETWEEN, IN</td>
<td>comparison</td>
</tr>
<tr>
<td>AND</td>
<td>conjunction</td>
</tr>
<tr>
<td>OR</td>
<td>inclusion</td>
</tr>
</tbody>
</table>

Table 2–3 Order of Operations

Operators with higher precedence are applied first. For example, both of the following expressions yield 8 because division has a higher precedence than addition:

\[
\begin{align*}
5 + 12 / 4 &= 8 \\
12 / 4 + 5 &= 8
\end{align*}
\]

Operators with the same precedence are applied in no particular order.

You can use parentheses to control the order of evaluation. For example, the following expression yields 7, not 11, because parentheses override the default operator precedence:

\[
(8 + 6) / 2 = 7
\]

In the next example, the subtraction is done before the division because the most deeply nested subexpression is always evaluated first:

\[
100 + (20 / 5 + (7 - 3)) = 100 + (4 + 4) = 108
\]

The following example shows that you can always use parentheses to improve readability, even when they are not needed:

\[
(salary * 0.05) + (commission * 0.25)
\]
Logical Operators

The logical operators AND, OR, and NOT follow the tri-state logic of the truth tables in Figure 2–3. AND and OR are binary operators; NOT is a unary operator.

NOT

\[
\begin{array}{cccc}
\text{NOT} & \text{TRUE} & \text{FALSE} & \text{NULL} \\
\text{FALSE} & \text{TRUE} & \text{NULL} \\
\end{array}
\]

AND

\[
\begin{array}{cccc}
\text{AND} & \text{TRUE} & \text{FALSE} & \text{NULL} \\
\text{TRUE} & \text{TRUE} & \text{FALSE} & \text{NULL} \\
\text{FALSE} & \text{FALSE} & \text{FALSE} & \text{FALSE} \\
\text{NULL} & \text{NULL} & \text{FALSE} & \text{NULL} \\
\end{array}
\]

OR

\[
\begin{array}{cccc}
\text{OR} & \text{TRUE} & \text{FALSE} & \text{NULL} \\
\text{TRUE} & \text{TRUE} & \text{TRUE} & \text{TRUE} \\
\text{FALSE} & \text{TRUE} & \text{FALSE} & \text{NULL} \\
\text{NULL} & \text{NULL} & \text{TRUE} & \text{NULL} \\
\end{array}
\]

Figure 2–3 Truth Tables

As the truth tables show, AND returns the value TRUE only if both its operands are true. On the other hand, OR returns the value TRUE if either of its operands is true. NOT returns the opposite value (logical negation) of its operand. For example, NOT TRUE returns FALSE.

NOT NULL returns NULL because nulls are indeterminate. It follows that if you apply the NOT operator to a null, the result is also indeterminate. Be careful. Nulls can cause unexpected results; see “Handling Nulls” on page 2–34.

Order of Evaluation

When you do not use parentheses to specify the order of evaluation, operator precedence determines the order. Compare the following expressions:

\[
\text{NOT (valid AND done)} \quad \mid \quad \text{NOT valid AND done}
\]

If the Boolean variables valid and done have the value FALSE, the first expression yields TRUE. However, the second expression yields FALSE because NOT has a higher precedence than AND; therefore, the second expression is equivalent to

\[
\text{(NOT valid) AND done}
\]
Comparison Operators

Comparison operators compare one expression to another. The result is always TRUE, FALSE, or NULL. Typically, you use comparison operators in the WHERE clause of SQL data manipulation statements and in conditional control statements.

Relational Operators

The relational operators allow you to compare arbitrarily complex expressions. The following list gives the meaning of each operator:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>is equal to</td>
</tr>
<tr>
<td>!, !=, ~</td>
<td>is not equal to</td>
</tr>
<tr>
<td>&lt;</td>
<td>is less than</td>
</tr>
<tr>
<td>&gt;</td>
<td>is greater than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>is less than or equal to</td>
</tr>
<tr>
<td>&gt;=</td>
<td>is greater than or equal to</td>
</tr>
</tbody>
</table>

IS NULL Operator

The IS NULL operator returns the Boolean value TRUE if its operand is null or FALSE if it is not null. Comparisons involving nulls always yield NULL. Therefore, to test for nullity (the state of being null), do not use the statement

```
IF variable = NULL THEN ...
```

Instead, use the following statement:

```
IF variable IS NULL THEN ...
```

LIKE Operator

You use the LIKE operator to compare a character value to a pattern. Case is significant. LIKE returns the Boolean value TRUE if the character patterns match or FALSE if they do not match.

The patterns matched by LIKE can include two special—purpose characters called wildcards. An underscore (_) matches exactly one character; a percent sign (%) matches zero or more characters. For example, if the value of `ename` is ‘JOHNSON’, the following expression yields TRUE:

```
ename LIKE 'J%SON'
```
BETWEEN Operator  The BETWEEN operator tests whether a value lies in a specified range. It means "greater than or equal to low value and less than or equal to high value." For example, the following expression yields FALSE:

45 BETWEEN 38 AND 44

IN Operator  The IN operator tests set membership. It means "equal to any member of." The set can contain nulls, but they are ignored. For example, the following statement does not delete rows in which the ename column is null:

DELETE FROM emp WHERE ename IN (NULL, 'KING', 'FORD');

Furthermore, expressions of the form

value NOT IN set

yield FALSE if the set contains a null. For example, instead of deleting rows in which the ename column is not null and not 'KING', the following statement deletes no rows:

DELETE FROM emp WHERE ename NOT IN (NULL, 'KING');

Concatenation Operator  The concatenation operator (||) appends one string to another. For example, the expression

'suit' || 'case'

returns the value 'suitcase'.

If both operands have datatype CHAR, the concatenation operator returns a CHAR value. Otherwise, it returns a VARCHAR2 value.

Boolean Expressions  PL/SQL lets you compare variables and constants in both SQL and procedural statements. These comparisons, called Boolean expressions, consist of simple or complex expressions separated by relational operators. Often, Boolean expressions are connected by the logical operators AND, OR, and NOT. A Boolean expression always yields TRUE, FALSE, or NULL.

In a SQL statement, Boolean expressions let you specify the rows in a table that are affected by the statement. In a procedural statement, Boolean expressions are the basis for conditional control. There are three kinds of Boolean expressions: arithmetic, character, and date.
Arithmetic

You can use the relational operators to compare numbers for equality or inequality. Comparisons are quantitative; that is, one number is greater than another if it represents a larger quantity. For example, given the assignments

\[
\text{number1} := 75; \\
\text{number2} := 70;
\]

the following expression yields TRUE:

\[
\text{number1} > \text{number2}
\]

Character

Likewise, you can compare character values for equality or inequality. Comparisons are based on the collating sequence used for the database character set. A **collating sequence** is an internal ordering of the character set, in which a range of numeric codes represents the individual characters. One character value is greater than another if its internal numeric value is larger. For example, given the assignments

\[
\text{string1} := \text{‘Kathy’}; \\
\text{string2} := \text{‘Kathleen’};
\]

the following expression yields TRUE:

\[
\text{string1} > \text{string2}
\]

However, there are semantic differences between the CHAR and VARCHAR2 base types that come into play when you compare character values. For more information, refer to Appendix C.

Date

You can also compare dates. Comparisons are chronological; that is, one date is greater than another if it is more recent. For example, given the assignments

\[
\text{date1} := \text{‘01–JAN–91’}; \\
\text{date2} := \text{‘31–DEC–90’};
\]

the following expression yields TRUE:

\[
\text{date1} > \text{date2}
\]

Guidelines

In general, do not compare real numbers for exact equality or inequality. Real numbers are stored as approximate values. So, for example, the following IF condition might not yield TRUE:

\[
\text{count} := 1; \\
\text{IF count} = 1.0 \text{ THEN ...}
\]
It is a good idea to use parentheses when doing comparisons. For example, the following expression is illegal because $100 < \text{tax}$ yields TRUE or FALSE, which cannot be compared with the number 500:

$100 < \text{tax} < 500$ –– illegal

The debugged version follows:

$\text{(100 < tax)} \text{ AND (tax < 500)}$

A Boolean variable is itself either true or false. So, comparisons with the Boolean values TRUE and FALSE are redundant. For example, assuming the variable done has the datatype BOOLEAN, the IF statement

IF done = TRUE THEN ...  

can be simplified as follows:

IF done THEN ...

**Handling Nulls**

When working with nulls, you can avoid some common mistakes by keeping in mind the following rules:

- comparisons involving nulls always yield NULL
- applying the logical operator NOT to a null yields NULL
- in conditional control statements, if the condition yields NULL, its associated sequence of statements is not executed

In the example below, you might expect the sequence of statements to execute because $x$ and $y$ seem unequal. But, nulls are indeterminate. Whether or not $x$ is equal to $y$ is unknown. Therefore, the IF condition yields NULL and the sequence of statements is bypassed.

```
x := 5;
y := NULL;
...
IF x != y THEN -- yields NULL, not TRUE
    sequence_of_statements; -- not executed
END IF;
```

In the next example, you might expect the sequence of statements to execute because $a$ and $b$ seem equal. But, again, that is unknown, so the IF condition yields NULL and the sequence of statements is bypassed.

```
a := NULL;
b := NULL;
...
IF a = b THEN -- yields NULL, not TRUE
    sequence_of_statements; -- not executed
END IF;
```
NOT Operator
Recall that applying the logical operator NOT to a null yields NULL. Thus, the following two statements are not always equivalent:

```
IF x > y THEN     |     IF NOT x > y THEN
  high := x;     |         high := y;
ELSE              |     ELSE
  high := y;     |         high := x;
END IF;           |     END IF;
```

The sequence of statements in the ELSE clause is executed when the IF condition yields FALSE or NULL. So, if either or both x and y are null, the first IF statement assigns the value of y to high, but the second IF statement assigns the value of x to high. If neither x nor y is null, both IF statements assign the same value to high.

Zero–Length Strings
PL/SQL treats any zero–length string like a null. This includes values returned by character functions and Boolean expressions. For example, the following statements assign nulls to the target variables:

```
null_string := TO_VARCHAR2('');
zip_code := SUBSTR(address, 25, 0);
valid := (name != '');
```

So, use the IS NULL operator to test for null strings, as follows:

```
IF my_string IS NULL THEN ...
```

Concatenation Operator
The concatenation operator ignores null operands. For example, the expression

```
‘apple’ || NULL || NULL || ‘sauce’
```

returns the value ‘applesauce’.

Functions
If a null argument is passed to a built–in function, a null is returned except in the following cases.

The function DECODE compares its first argument to one or more search expressions, which are paired with result expressions. Any search or result expression can be null. If a search is successful, the corresponding result is returned. In the following example, if the column rating is null, DECODE returns the value 1000:

```
SELECT DECODE(rating, NULL, 1000, 'C', 2000, 'B', 4000, 'A', 5000)
INTO credit_limit FROM accts WHERE acctno = my_acctno;
```

The function NVL returns the value of its second argument if its first argument is null. In the example below, if hire_date is null, NVL returns the value of SYSDATE. Otherwise, NVL returns the value of hire_date:

```
start_date := NVL(hire_date, SYSDATE);
```
The function REPLACE returns the value of its first argument if its second argument is null, whether the optional third argument is present or not. For instance, after the assignment

```sql
new_string := REPLACE(old_string, NULL, my_string);
```

the values of `old_string` and `new_string` are the same.

If its third argument is null, REPLACE returns its first argument with every occurrence of its second argument removed. For example, after the assignments

```sql
syllabified_name := 'Gold–i–locks';
name := REPLACE(syllabified_name, '-', NULL);
```

the value of `name` is ‘Goldilocks’.

If its second and third arguments are null, REPLACE simply returns its first argument.

---

**Built-in Functions**

PL/SQL provides more than 70 powerful functions to help you manipulate data. These built-in functions fall into the following categories: error-reporting, number, character, conversion, date, and miscellaneous. Table 2–4 shows the functions in each category.

You can use every function in SQL statements except the error-reporting functions SQLCODE and SQLERRM. You can also use every function in procedural statements except the miscellaneous functions DECODE, DUMP, and VSIZE. Furthermore, you can nest function calls, as the following example shows:

```sql
SELECT TO_CHAR(TO_DATE('11-10-93', 'MM-DD-YYYY'), 'J') ...
```

The SQL group functions AVG, MIN, MAX, COUNT, SUM, STDDEV, and VARIANCE are not built into PL/SQL. Nevertheless, you can use them in SQL statements (but not in procedural statements).

For descriptions of the error-reporting functions, see Chapter 9. For descriptions of the other functions, see Oracle7 Server SQL Reference.

Table 2 – 4  Built-in Functions
PL/SQL Tables

PL/SQL provides two composite datatypes: TABLE and RECORD. This section discusses the TABLE type; the next section discusses the RECORD type.

Objects of type TABLE are called PL/SQL tables, which are modelled as (but not the same as) database tables. PL/SQL tables have one column and a primary key, neither of which can be named. The column can have any scalar datatype, but the primary key must have datatype BINARY_INTEGER. The primary key gives you array-like access to rows. Moreover, with the Oracle Call Interface (OCI) or the Oracle Precompilers, you can bind PL/SQL tables to host arrays.

Like the size of a database table, the size of a PL/SQL table is unconstrained. That is, the number of rows in a PL/SQL table can increase dynamically. So, your PL/SQL table grows as new rows are added.

Declaring PL/SQL Tables

PL/SQL tables must be declared in two steps. First, you define a TABLE type, then declare PL/SQL tables of that type. You can define TABLE types in the declarative part of any block, subprogram, or package using the syntax

```plsql
TYPE type_name IS TABLE OF 
  { column_type | variable%TYPE | table.column%TYPE } [NOT NULL]
INDEX BY BINARY_INTEGER;
```

where `type_name` is a type specifier used in subsequent declarations of PL/SQL tables and `column_type` is any scalar (not composite) datatype such as CHAR, DATE, or NUMBER. Notice that you can use the %TYPE attribute to specify a column datatype. In the following example, you define a TABLE type called `EnameTabTyp`:

```plsql
DECLARE
  TYPE EnameTabTyp IS TABLE OF emp.ename%TYPE
  INDEX BY BINARY_INTEGER;
```

The next example shows that you can add the NOT NULL constraint to a TABLE type definition and so prevent the assigning of nulls to PL/SQL tables of that type:

```plsql
DECLARE
  TYPE EnameTabTyp IS TABLE OF emp.ename%TYPE NOT NULL
  INDEX BY BINARY_INTEGER;
```

An initialization clause is not required (or allowed).
Once you define type `EnameTabTyp`, you can declare PL/SQL tables of that type, as follows:

```plsql
ename_tab EnameTabTyp;
```

The identifier `ename_tab` represents an entire PL/SQL table.

A PL/SQL table is unconstrained because its primary key can assume any value in the range of values defined for BINARY_INTEGER. As a result, you cannot initialize a PL/SQL table in its declaration. For example, the following declaration is illegal:

```plsql
ename_tab EnameTabTyp := ('CASEY', 'STUART', 'CHU');  -- illegal
```

PL/SQL tables follow the usual scoping and instantiation rules. (Instantiation is the creation of a new instance of a program object.) In a package, PL/SQL tables are instantiated when you first reference the package and cease to exist when you exit the application or end the database session. In a block or subprogram, they are instantiated when you enter the block or subprogram and cease to exist when you exit.

Like scalar variables, PL/SQL tables can be declared as the formal parameters of procedures and functions. The restrictions that apply to scalar parameters also apply to PL/SQL tables. Some packaged examples follow:

```plsql
PACKAGE emp_actions IS
    TYPE EnameTabTyp IS TABLE OF emp.ename%TYPE INDEX BY BINARY_INTEGER;
    TYPE SalTabTyp IS TABLE OF emp.sal%TYPE INDEX BY BINARY_INTEGER;
    ename_tab EnameTabTyp;
    sal_tab   SalTabTyp;
    ...
    PROCEDURE hire_batch(
        ename_tab EnameTabTyp,
        sal_tab   SalTabTyp,
        ...);
    PROCEDURE log_names(
        ename_tab EnameTabTyp,
        num       BINARY_INTEGER);
    ...
END emp_actions;
```

To define the behavior of formal parameters, you use parameter modes (see “Parameter Modes” on page 6–13). OUT parameters let you return values to the caller of a subprogram when you exit. If you exit successfully, PL/SQL assigns row values to the actual parameters. However, if you exit with an unhandled exception, PL/SQL does not assign row values to the actual parameters.
Referencing PL/SQL Tables

To reference rows in a PL/SQL table, you specify a primary key value using the array–like syntax

\[ \text{plsql_table_name(primary_key_value)} \]

where \text{primary_key_value} has datatype BINARY_INTEGER. For example, you reference the third row in PL/SQL table \text{ename_tab} as follows:

\[ \text{ename_tab(3)} \ldots \]

As the following example shows, the primary key value can be negative (for an exception, see “Using Host Arrays with PL/SQL Tables” on page 8–14.):

\[ \text{ename_tab(-5)} \ldots \]

You can assign the value of a PL/SQL expression to a specific row using the following syntax:

\[ \text{plsql_table_name(primary_key_value)} := \text{plsql_expression}; \]

In the next example, you assign the sum of variables \text{salary} and \text{increase} to the fifth row in PL/SQL table \text{sal_tab}:

\[ \text{sal_tab(5)} := \text{salary + increase}; \]

In the example below, you use a cursor FOR loop to load two PL/SQL tables. A cursor FOR loop implicitly declares its loop index as a record, opens the cursor associated with a given query, repeatedly fetches rows of values from the active set into fields in the record, then closes the cursor. (See “Using Cursor FOR Loops” on page 4–15.)

```
DECLARE
    TYPE EnameTabTyp IS TABLE OF emp.ename%TYPE
      INDEX BY BINARY_INTEGER;
    TYPE SalTabTyp IS TABLE OF emp.sal%TYPE
      INDEX BY BINARY_INTEGER;
    ename_tab EnameTabTyp;
    sal_tab   SalTabTyp;
    i         BINARY_INTEGER := 0;
PROCEDURE check_sals (rows  IN BINARY_INTEGER,
    names IN EnameTabTyp,
    sals  IN SalTabTyp) IS ...
BEGIN
    -- load employee names and salaries into PL/SQL tables
    FOR emprec IN (SELECT ename, sal FROM emp) LOOP
        i := i + 1;
        ename_tab(i) := emprec.ename;
        sal_tab(i) := emprec.sal;
    END LOOP;
    -- process the tables
    check_sals(i, ename_tab, sal_tab);
    ...
```

2 – 40 PL/SQL User’s Guide and Reference
In the next example, you use dot notation to reference the package `emp_actions` seen earlier in this section:

```plsql
DECLARE
  i BINARY_INTEGER := 0;
BEGIN
  -- load employee names into a PL/SQL table
  FOR emprec IN (SELECT ename FROM emp ORDER BY ename) LOOP
    i := i + 1;
    emp_actions.ename_tab(i) := emprec.ename;
  END LOOP;
  -- process the PL/SQL table
  emp_actions.log_names(emp_actions.ename_tab, i);
END;
```

Until a row is assigned a value, it does not exist. If you try to reference an uninitialized row, PL/SQL raises the predefined exception `NO_DATA_FOUND`, as the following example shows:

```plsql
DECLARE
  TYPE JobTabTyp IS TABLE OF CHAR(14)
    INDEX BY BINARY_INTEGER;
  job_tab JobTabTyp;
BEGIN
  job_tab(1) := 'CLERK';
  IF job_tab(2) = 'CLERK' THEN  -- raises NO_DATA_FOUND
    ...
  END IF;
  ...
EXCEPTION
  WHEN NO_DATA_FOUND THEN
    -- here because job_tab(2) does not exist
    ...
END;
```

Row references such as `job_tab(1)` are allowed as actual parameters in subprogram calls but are subject to the same restrictions as scalar variables.
Maintaining a Row Count

Remember, the size of a PL/SQL table is unconstrained. So, if you want to maintain a row count, you must declare a variable for that purpose. For example, you might declare an INTEGER variable named `row_count` to store the number of rows currently in your PL/SQL table.

What happens if a PL/SQL table grows too large? Consider the following example:

```sql
DECLARE
    TYPE DateTabTyp IS TABLE OF DATE
    INDEX BY BINARY_INTEGER;
    hiredate_tab  DateTabTyp;
    i BINARY_INTEGER := 0;
BEGIN
    /* Initialize PL/SQL table. */
    LOOP
        i := i + 1;
        hiredate_tab(i) := SYSDATE;
    EXIT WHEN statement omitted
    END LOOP;
    ...
END;
```

With each iteration of the basic loop, another row is added to the PL/SQL table. The loop cannot complete because it contains no EXIT WHEN statement. Eventually, PL/SQL runs out of memory and raises the predefined exception `STORAGE_ERROR`.

Inserting and Fetching Rows

You must use a loop to insert values from a PL/SQL table into a database column. And, you must use a cursor FOR loop to fetch values from a database column into a PL/SQL table. (No stream interface like that provided by the Oracle Precompilers for host arrays is available for PL/SQL tables.) For example, given the declarations

```sql
DECLARE
    TYPE EmpnoTabTyp IS TABLE OF NUMBER(4)
    INDEX BY BINARY_INTEGER;
    TYPE EnameTabTyp IS TABLE OF CHAR(10)
    INDEX BY BINARY_INTEGER;
    empno_tab EmpnoTabTyp;
    ename_tab EnameTabTyp;

    PROCEDURE insert_emp_data (rows IN BINARY_INTEGER,
                                empno_tab IN EmpnoTabTyp,
                                ename_tab IN EnameTabTyp, ...) IS
```
BEgin
   FOR i IN 1..rows LOOP
       INSERT INTO emp (empno, ename, ...) VALUES (empno_tab(i), ename_tab(i), ...);
   END LOOP;
END;

Similarly, you might use the next procedure to fetch all rows from the emp database table into PL/SQL tables empno_tab and ename_tab:

PROCEDURE fetch_emp_data (
    rows      OUT BINARY_INTEGER,
    empno_tab OUT EmpnoTabTyp,
    ename_tab OUT EnameTabTyp, ...) IS
BEGIN
    rows := 0;
    FOR emprec IN (SELECT * FROM emp) LOOP
        rows := rows + 1;
        empno_tab(rows) := emprec.empno;
        ename_tab(rows) := emprec.ename;
        ...
    END LOOP;
END;

You cannot reference PL/SQL tables in the INTO clause. Therefore, you cannot use a SELECT or FETCH statement to load a PL/SQL table. For example, the following SELECT statement is illegal:

SELECT empno, ename INTO empno_tab, ename_tab ... -- illegal

Deleting Rows

The DELETE statement cannot specify PL/SQL tables, so you cannot delete individual rows from a PL/SQL table. Assigning NULL to a row as follows does not work because the row remains:

sal_tab(3) := NULL;

However, you can use a simple workaround to delete an entire PL/SQL table. Simply assign NULL to it, as shown in the following example:

DECLARE
    TYPE NumTabTyp IS TABLE OF NUMBER INDEX BY BINARY_INTEGER;
    sal_tab NumTabTyp;
BEGIN
    /* Load salary table. */
    FOR i IN 1..50 LOOP
        sal_tab(i) := i;
    END LOOP;
    ...
    sal_tab := NULL; -- deletes sal_tab table
    IF sal_tab(3) ... -- raises NO_DATA_FOUND
User-Defined Records

You can use the %ROWTYPE attribute to declare a record that represents a row in a table or a row fetched from a cursor or cursor variable. However, you cannot specify the datatypes of fields in the record or define fields of your own. The composite datatype RECORD lifts those restrictions.

As you might expect, objects of type RECORD are called records. Unlike PL/SQL tables, records have uniquely named fields, which can have different datatypes. For example, suppose you have different kinds of data about an employee such as name, salary, hire date, and so on. This data is dissimilar in type but logically related. A record that contains such fields as the name, salary, and hire date of an employee would let you treat the data as a logical unit.

Declaring Records

Like PL/SQL tables, records must be declared in two steps. First, you define a RECORD type, then declare user-defined records of that type. You can define RECORD types in the declarative part of any block, subprogram, or package using the syntax

```plsql
TYPE type_name IS RECORD (
    field_name1 field_type [NOT NULL {:= | DEFAULT} expr],
    field_name2 field_type [NOT NULL {:= | DEFAULT} expr], ...
);```

where `type_name` is a type specifier used in subsequent declarations of records and `field_type` stands for the following syntax:

```plsql
{  datatype_name
| variable%TYPE
| record_variable%TYPE
| table.column%TYPE
| table%ROWTYPE
| cursor%ROWTYPE
| cursor_variable%ROWTYPE }
```

You can use the attributes %TYPE and %ROWTYPE to specify field types. In the following example, you define a RECORD type named `DeptRecTyp`:

```plsql
DECLARE
    TYPE DeptRecTyp IS RECORD (
        deptno NUMBER(2) NOT NULL := 99,
        dname dept.dname%TYPE,
        loc dept.loc%TYPE);
```

Notice that the field declarations are like variable declarations. Each field has a unique name and specific datatype. You can add the NOT NULL constraint to any field declaration and so prevent the assigning of nulls to that field. Fields declared as NOT NULL must be initialized.
Once you define type `DeptRecTyp`, you can declare records of that type, as follows:

depth_rec DeptRecTyp;

The identifier `dept_rec` represents an entire record.

Unlike PL/SQL tables, a record type can be initialized in its definition, as this example shows:

```
DECLARE
    TYPE TimeTyp IS RECORD (
        second SMALLINT := 0,
        minute SMALLINT := 0,
        hour   SMALLINT := 0);
```

When you declare a record of type `TimeTyp`, its three fields assume an initial value of zero.

User–defined records follow the usual scoping and instantiation rules. Like scalar variables, user–defined records can be declared as the formal parameters of procedures and functions. An example follows:

```
PACKAGE emp_actions IS
    TYPE EmpRecTyp IS RECORD (
        empno NUMBER(4) NOT NULL := 1001,
        ename VARCHAR2(10),
        job   VARCHAR2(14), ... );
    ...
    PROCEDURE hire_employee (emp_rec EmpRecTyp);
    ...
END emp_actions;
```

**Referencing Records**

To reference individual fields in a record, you use dot notation and the following syntax:

```
record_name.field_name
```

For example, you reference the `ename` field in the `emp_rec` record as follows:

```
emp_rec.ename ...
```

You can assign the value of a PL/SQL expression to a specific field by using the following syntax:

```
record_name.field_name := plsql_expression;
```

In the next example, you convert an employee name to uppercase:

```
emp_rec.ename := UPPER(emp_rec.ename);
```
Instead of assigning values separately to each field in a record, you can assign values to all fields at once. This can be done in two ways. First, you can assign one record to another if they have the same datatype. For example, given the declarations

```plsql
DECLARE
  TYPE  DeptRecTyp IS RECORD(...);
  dept_rec1 DeptRecTyp;
  dept_rec2 DeptRecTyp;
the following assignment is legal:

  dept_rec1 := dept_rec2;
```

Even if their fields match exactly, records of different types cannot be assigned to each other. Furthermore, a user–defined record and a `%ROWTYPE` record always have different datatypes, as the following example shows:

```plsql
DECLARE
  TYPE DeptRecTyp IS RECORD(
    deptno NUMBER(2),
    dname VARCHAR2(14),
    loc VARCHAR2(13));
  dept_rec1 DeptRecTyp;
  dept_rec2 dept%ROWTYPE;

BEGIN
  dept_rec1 := dept_rec2;  -- illegal
```

Second, you can use the `SELECT` or `FETCH` statement to fetch column values into a record, as the example below shows. Just make sure the column names appear in the same order as the fields in your record.

```plsql
DECLARE
  TYPE DeptRecTyp IS RECORD(
    deptno NUMBER(2),
    dname VARCHAR2(14),
    loc VARCHAR2(13));
  dept_rec DeptRecTyp;

BEGIN
  SELECT deptno, dname, loc INTO dept_rec
    FROM dept WHERE deptno = 30;
```

However, you cannot use the `INSERT` statement to insert user–defined records into a database table. So, the following statement is illegal:

```plsql
INSERT INTO dept VALUES (dept_rec);  -- illegal
```
Also, you cannot assign a list of values to a record by using an assignment statement. Therefore, the following syntax is illegal:

```sql
record_name := (value1, value2, value3, ...);  -- illegal
```

Finally, records cannot be tested for equality, inequality, or nullity. For instance, the following IF conditions are illegal:

```sql
IF dept_rec1 = dept_rec2 THEN ...  -- illegal
IF emp_rec IS NULL THEN ...  -- illegal
```

**Nested Records**

PL/SQL lets you declare and reference *nested* records. That is, a record can be the component of another record, as this example shows:

```sql
DECLARE
    TYPE TimeTyp IS RECORD(
        minute SMALLINT,
        hour   SMALLINT);
    TYPE MeetingTyp IS RECORD(
        day    DATE,
        time   TimeTyp,     -- nested record
        place  VARCHAR2(20),
        purpose VARCHAR2(50));
    TYPE PartyTyp IS RECORD(
        day    DATE,
        time   TimeTyp,        -- nested record
        loc    VARCHAR2(15));
    meeting MeetingTyp;
    seminar MeetingTyp;
    party   PartyTyp;
    ...
BEGIN
    meeting.day := '26–JUN–91';
    meeting.time.minute := 45;
    meeting.time.hour := 10;
    ...
END;
```

The next example shows that you can assign one nested record to another if they have the same datatype:

```sql
seminar.time := meeting.time;
```

Such assignments are allowed even if the containing records have different datatypes, as the following example shows:

```sql
party.time := meeting.time;
```
Using Records

The RECORD type lets you collect information about the attributes of an object. It is easy to manipulate the information because you can refer to the object as a whole. In the following example, you collect accounting figures from database tables named assets and liabilities, then use ratio analysis to compare the performance of two subsidiary companies:

```
DECLARE
  TYPE FiguresTyp IS RECORD (
    cash                  REAL,
    marketable_securities REAL,
    accounts_receivable   REAL,
    inventories           REAL,
    accounts_payable      REAL,
    notes                 REAL,
    employment_costs      REAL,
    accrued_taxes         REAL,
    dividends_payable     REAL,
    short_term_debt       REAL);
  sub1_figs FiguresTyp;
  sub2_figs FiguresTyp;
  ...  
  FUNCTION acid_test (figs FiguresTyp) RETURN REAL IS
    current_liabilities REAL;
    BEGIN
      current_liabilities := figs.accounts_payable + figs.notes
        + figs.employment_costs + figs.accrued_taxes
        + figs.dividends_payable + figs.short_term_debt;
      RETURN (figs.cash + figs.marketable_securities
        + figs.accounts_receivable) / current_liabilities;
    END acid_test;
    ...  
    BEGIN
      SELECT cash, mkt_sec, accts_rec, ... INTO sub1_figs
        FROM assets, liabilities
        WHERE assets.sub = 1 AND liabilities.sub = 1;
      SELECT cash, mkt_sec, accts_rec, ... INTO sub2_figs
        FROM assets, liabilities
        WHERE assets.sub = 2 AND liabilities.sub = 2;
      ...  
      IF acid_test(sub1_figs) > acid_test(sub2_figs) THEN ...
      ...  
    END;
```

Notice how easy it is to pass the collected figures to the function acid_test, which computes a financial ratio.
User-Defined Subtypes

Each PL/SQL base type specifies a set of values and a set of operations applicable to objects of that type. Subtypes specify the same set of operations as their base type but only a subset of its values. Thus, a subtype does not introduce a new type; it merely places an optional constraint on its base type.

PL/SQL predefines several subtypes in package STANDARD. For example, PL/SQL predefines the subtype CHARACTER, as follows:

```plsql
SUBTYPE CHARACTER IS CHAR;
```

The subtype CHARACTER specifies the same set of values as its base type CHAR. Thus, CHARACTER is an unconstrained subtype.

Subtypes can increase reliability, provide compatibility with ANSI/ISO and IBM types, and improve readability by indicating the intended use of constants and variables.

Defining Subtypes

You can define your own subtypes in the declarative part of any PL/SQL block, subprogram, or package using the syntax

```plsql
SUBTYPE subtype_name IS base_type;
```

where `subtype_name` is a type specifier used in subsequent declarations and `base_type` stands for the following syntax:

```
{ datatype_name
 | variable%TYPE
 | record_variable%TYPE
 | plsql_table%TYPE
 | table.column%TYPE
 | table%ROWTYPE
 | cursor%ROWTYPE
 | cursor_variable%ROWTYPE }
```

For example, all of the following subtype definitions are legal:

```plsql
DECLARE
  SUBTYPE EmpDate IS DATE;           -- based on DATE type
  SUBTYPE Counter IS NATURAL;        -- based on NATURAL subtype
  TYPE NameTab IS TABLE OF VARCHAR2(10)
   INDEX BY BINARY_INTEGER;
  SUBTYPE EnameTab IS NameTab;       -- based on TABLE type
  TYPE TimeTyp IS RECORD
   (minute SMALLINT, hour SMALLINT);
  SUBTYPE Clock IS TimeTyp;          -- based on RECORD type
  SUBTYPE ID_Num IS emp.empno%TYPE;  -- based on column type
  CURSOR c1 IS SELECT * FROM dept;
  SUBTYPE Dept_Rec IS c1%ROWTYPE;    -- based on cursor rowtype
```
However, you cannot specify a constraint on the base type. For example, the following definitions are illegal:

```sql
DECLARE
  SUBTYPE Accumulator IS NUMBER(7,2); -- illegal; must be NUMBER
  SUBTYPE Delimiter IS CHAR(1);     -- illegal; must be CHAR
  SUBTYPE Word IS VARCHAR2(15);    -- illegal
END;
```

Although you cannot define constrained subtypes directly, you can use a simple workaround to define size-constrained subtypes indirectly. Simply declare a size-constrained variable, then use %TYPE to provide its datatype, as shown in the following example:

```sql
DECLARE
  temp VARCHAR2(15);
  SUBTYPE Word IS temp%TYPE; -- maximum size of Word is 15
END;
```

Likewise, if you define a subtype using %TYPE to provide the datatype of a database column, the subtype adopts the size constraint (if any) of the column. However, the subtype does not adopt other kinds of constraints such as NOT NULL.

### Using Subtypes

Once you define a subtype, you can declare objects of that type. In the example below, you declare two variables of type `Counter`. Notice how the subtype name indicates the intended use of the variables.

```sql
DECLARE
  SUBTYPE Counter IS NATURAL;
  rows      Counter;
  employees Counter;
END;
```

The following example shows that you can constrain a user-defined subtype when declaring variables of that type:

```sql
DECLARE
  SUBTYPE Accumulator IS NUMBER;
  total Accumulator(7,2);
END;
```

Subtypes can increase reliability by detecting out-of-range values. In the example below, you restrict the subtype `Scale` to storing integers in the range $-9 .. 9$. If your program tries to store a number outside that range in a `Scale` variable, PL/SQL raises an exception.

```sql
DECLARE
  temp NUMBER(1,0);
  SUBTYPE Scale IS temp%TYPE;
  x_axis Scale;    -- magnitude range is $-9 .. 9$
  y_axis Scale;
BEGIN
  x_axis := 10;    -- raises VALUE_ERROR
END;
```
An unconstrained subtype is interchangeable with its base type. For example, given the following declarations, the value of \( \text{amount} \) can be assigned to \( \text{total} \) without conversion:

```sql
DECLARE
  SUBTYPE Accumulator IS NUMBER;
  amount NUMBER(7,2);
  total  Accumulator;
BEGIN
  ...
  total := amount;
END;
```

Different subtypes are interchangeable if they have the same base type. For instance, given the following declarations, the value of \( \text{finished} \) can be assigned to \( \text{debugging} \):

```sql
DECLARE
  SUBTYPE Sentinel IS BOOLEAN;
  SUBTYPE Switch IS BOOLEAN;
  finished  Sentinel;
  debugging Switch;
BEGIN
  ...
  debugging := finished;
END;
```

Different subtypes are also interchangeable if their base types are in the same datatype family. For example, given the following declarations, the value of \( \text{verb} \) can be assigned to \( \text{sentence} \):

```sql
DECLARE
  SUBTYPE Word IS CHAR;
  SUBTYPE Text IS VARCHAR2;
  verb     Word;
  sentence Text;
BEGIN
  ...
  sentence := verb;
END;
```
Control Structures

_One ship drives east and another drives west_
_With the selfsame winds that blow._
_`Tis the set of the sails and not the gales_
_Which tells us the way to go._

Ella Wheeler Wilcox

This chapter shows you how to structure the flow of control through a PL/SQL program. You learn how statements are connected by simple but powerful control structures that have a single entry and exit point. Collectively, these structures can handle any situation. And, their proper use leads naturally to a well-structured program.
Overview

According to the *structure theorem*, any computer program can be written using the basic control structures shown in Figure 3–1. They can be combined in any way necessary to deal with a given problem.

![Control Structures Diagram]

**Figure 3–1 Control Structures**

The selection structure tests a condition, then executes one sequence of statements instead of another, depending on whether the condition is true or false. A *condition* is any variable or expression that returns a Boolean value (TRUE, FALSE, or NULL). The iteration structure executes a sequence of statements repeatedly as long as a condition holds true. The sequence structure simply executes a sequence of statements in the order in which they occur.

---

**Conditional Control: IF Statements**

Often, it is necessary to take alternative actions depending on circumstances. The IF statement lets you execute a sequence of statements conditionally. That is, whether the sequence is executed or not depends on the value of a condition. There are three forms of IF statements: IF–THEN, IF–THEN–ELSE, and IF–THEN–ELSIF.

**IF–THEN**

The simplest form of IF statement associates a condition with a sequence of statements enclosed by the keywords THEN and END IF (not ENDIF), as follows:

```sql
IF condition THEN
    sequence_of_statements;
END IF;
```
The sequence of statements is executed only if the condition yields TRUE. If the condition yields FALSE or NULL, the IF statement does nothing. In either case, control passes to the next statement. An example follows:

```
IF sales > quota THEN
    compute_bonus(empid);
    UPDATE payroll SET pay = pay + bonus WHERE empno = emp_id;
END IF;
```

You might want to place brief IF statements on a single line, as in
```
IF x > y THEN high := x; END IF;
```

### IF–THEN–ELSE

The second form of IF statement adds the keyword ELSE followed by an alternative sequence of statements, as follows:

```
IF condition THEN
    sequence_of_statements1;
ELSE
    sequence_of_statements2;
END IF;
```

The sequence of statements in the ELSE clause is executed only if the condition yields FALSE or NULL. Thus, the ELSE clause ensures that a sequence of statements is executed. In the following example, the first or second UPDATE statement is executed when the condition is true or false, respectively:

```
IF trans_type = 'CR' THEN
    UPDATE accounts SET balance = balance + credit WHERE ...
ELSE
    UPDATE accounts SET balance = balance – debit WHERE ...
END IF;
```

The THEN and ELSE clauses can include IF statements. That is, IF statements can be nested, as the following example shows:

```
IF trans_type = 'CR' THEN
    UPDATE accounts SET balance = balance + credit WHERE ...
ELSE
    IF new_balance >= minimum_balance THEN
        UPDATE accounts SET balance = balance – debit WHERE ...
    ELSE
        RAISE insufficient_funds;
    END IF;
END IF;
```
Sometimes you want to select an action from several mutually exclusive alternatives. The third form of IF statement uses the keyword ELSIF (not ELSEIF) to introduce additional conditions, as follows:

```sql
IF condition1 THEN
  sequence_of_statements1;
ELSIF condition2 THEN
  sequence_of_statements2;
ELSE
  sequence_of_statements3;
END IF;
```

If the first condition yields FALSE or NULL, the ELSIF clause tests another condition. An IF statement can have any number of ELSIF clauses; the final ELSE clause is optional. Conditions are evaluated one by one from top to bottom. If any condition yields TRUE, its associated sequence of statements is executed and control passes to the next statement. If all conditions yield FALSE or NULL, the sequence in the ELSE clause is executed. Consider the following example:

```sql
IF sales > 50000 THEN
  bonus := 1500;
ELSIF sales > 35000 THEN
  bonus := 500;
ELSE
  bonus := 100;
END IF;
INSERT INTO payroll VALUES (emp_id, bonus, ...);
```

If the value of `sales` is more than 50000, the first and second conditions are true. Nevertheless, `bonus` is assigned the proper value of 1500 because the second condition is never tested. When the first condition yields TRUE, its associated statement is executed and control passes to the INSERT statement.
Guidelines

Avoid clumsy IF statements like those in the following example:

DECLARE
  ...
  overdrawn  BOOLEAN;
BEGIN
  ...
  IF new_balance < minimum_balance THEN
    overdrawn := TRUE;
  ELSE
    overdrawn := FALSE;
  END IF;
  ...
  IF overdrawn = TRUE THEN
    RAISE insufficient_funds;
  END IF;
END;

This code disregards two useful facts. First, the value of a Boolean expression can be assigned directly to a Boolean variable. So, you can replace the first IF statement with a simple assignment, as follows:

overdrawn := new_balance < minimum_balance;

Second, a Boolean variable is itself either true or false. So, you can simplify the condition in the second IF statement, as follows:

IF overdrawn THEN ...

When possible, use the ELSIF clause instead of nested IF statements. That way, your code will be easier to read and understand. Compare the following IF statements:

<table>
<thead>
<tr>
<th>IF condition1 THEN statement1;</th>
<th>IF condition1 THEN statement1;</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELSE IF condition2 THEN statement2;</td>
<td>ELSE ELSIF condition2 THEN statement2;</td>
</tr>
<tr>
<td>ELSE IF condition3 THEN statement3;</td>
<td>ELSE ELSIF condition3 THEN statement3;</td>
</tr>
<tr>
<td>END IF; END IF; END IF;</td>
<td>END IF; END IF; END IF;</td>
</tr>
</tbody>
</table>

These statements are logically equivalent, but the first statement obscures the flow of logic, whereas the second statement reveals it.
Iterative Control: LOOP and EXIT Statements

LOOP statements let you execute a sequence of statements multiple times. There are three forms of LOOP statements: LOOP, WHILE–LOOP, and FOR–LOOP.

**LOOP**

The simplest form of LOOP statement is the basic (or infinite) loop, which encloses a sequence of statements between the keywords LOOP and END LOOP, as follows:

```
LOOP
  sequence_of_statements;
END LOOP;
```

With each iteration of the loop, the sequence of statements is executed, then control resumes at the top of the loop. If further processing is undesirable or impossible, you can use the EXIT statement to complete the loop. You can place one or more EXIT statements anywhere inside a loop, but nowhere outside a loop. There are two forms of EXIT statements: EXIT and EXIT–WHEN.

**EXIT**

The EXIT statement forces a loop to complete unconditionally. When an EXIT statement is encountered, the loop completes immediately and control passes to the next statement. An example follows:

```
LOOP
  ...
  IF credit_rating < 3 THEN
    ...
    EXIT;  -- exit loop immediately
  END IF;
END LOOP;
-- control resumes here
```

The next example shows that you cannot use the EXIT statement to complete a PL/SQL block:

```
BEGIN
  ...
  IF credit_rating < 3 THEN
    ...
    EXIT;  -- illegal
  END IF;
END;
```

Remember, the EXIT statement must be placed inside a loop. To complete a PL/SQL block before its normal end is reached, you can use the RETURN statement (see “RETURN Statement” on page 6 – 7).
EXIT–WHEN

The EXIT–WHEN statement allows a loop to complete conditionally. When the EXIT statement is encountered, the condition in the WHEN clause is evaluated. If the condition yields TRUE, the loop completes and control passes to the next statement after the loop. An example follows:

```
LOOP
  FETCH c1 INTO ...  
  EXIT WHEN c1%NOTFOUND; -- exit loop if condition is true
  ...
END LOOP;
CLOSE c1;
```

Until the condition yields TRUE, the loop cannot complete. So, statements within the loop must change the value of the condition. In the last example, if the FETCH statement returns a row, the condition yields FALSE. When the FETCH statement fails to return a row, the condition yields TRUE, the loop completes, and control passes to the CLOSE statement.

The EXIT–WHEN statement replaces a simple IF statement. For example, compare the following statements:

```
IF count > 100 THEN     |     EXIT WHEN count > 100;
  EXIT;                |     END IF;
END IF;                 |
```

These statements are logically equivalent, but the EXIT–WHEN statement is easier to read and understand.

Loop Labels

Like PL/SQL blocks, loops can be labeled. The label, an undeclared identifier enclosed by double angle brackets, must appear at the beginning of the LOOP statement, as follows:

```
<<label_name>>
LOOP
  sequence_of_statements;
END LOOP;
```

Optionally, the label name can also appear at the end of the LOOP statement, as the following example shows:

```
<<my_loop>>
LOOP
  ...
END LOOP my_loop;
```

When you nest labeled loops, you can use ending label names to improve readability.
With either form of EXIT statement, you can complete not only the current loop, but any enclosing loop. Simply label the enclosing loop that you want to complete. Then, use the label in an EXIT statement, as follows:

```
<<outer>>
LOOP
  ...
  LOOP
    ...
    EXIT outer WHEN ... -- exit both loops
    END LOOP;
  ...
END LOOP outer;
```

Every enclosing loop up to and including the labeled loop is exited.

**WHILE-LOOP**

The WHILE-LOOP statement associates a condition with a sequence of statements enclosed by the keywords LOOP and END LOOP, as follows:

```
WHILE condition LOOP
  sequence_of_statements;
END LOOP;
```

Before each iteration of the loop, the condition is evaluated. If the condition yields TRUE, the sequence of statements is executed, then control resumes at the top of the loop. If the condition yields FALSE or NULL, the loop is bypassed and control passes to the next statement. An example follows:

```
WHILE total <= 25000 LOOP
  ...
  SELECT sal INTO salary FROM emp WHERE ...
  total := total + salary;
END LOOP;
```

The number of iterations depends on the condition and is unknown until the loop completes. Since the condition is tested at the top of the loop, the sequence might execute zero times. In the last example, if the initial value of `total` is greater than 25000, the condition yields FALSE and the loop is bypassed.

Some languages have a LOOP UNTIL or REPEAT UNTIL structure, which tests the condition at the bottom of the loop instead of at the top. Therefore, the sequence of statements is executed at least once. PL/SQL has no such structure, but you can easily build one, as follows:

```
LOOP
  sequence_of_statements;
  EXIT WHEN boolean_expression;
END LOOP;
```
To ensure that a WHILE loop executes at least once, use an initialized Boolean variable in the condition, as follows:

```plaintext
done := FALSE;
WHILE NOT done LOOP
  sequence_of_statements;
  done := boolean_expression;
END LOOP;
```

A statement inside the loop must assign a new value to the Boolean variable. Otherwise, you have an infinite loop. For example, the following LOOP statements are logically equivalent:

```plaintext
WHILE TRUE LOOP     |     LOOP
  ...              |        ...
END LOOP;           |     END LOOP;
```

Whereas the number of iterations through a WHILE loop is unknown until the loop completes, the number of iterations through a FOR loop is known before the loop is entered. FOR loops iterate over a specified range of integers. (Cursor FOR loops, which iterate over the active set of a cursor, are discussed in Chapter 4.) The range is part of an iteration scheme, which is enclosed by the keywords FOR and LOOP. The syntax follows:

```plaintext
FOR counter IN [REVERSE] lower_bound..higher_bound LOOP
  sequence_of_statements;
END LOOP;
```

The range is evaluated when the FOR loop is first entered and is never re-evaluated. As the next example shows, the sequence of statements is executed once for each integer in the range. After each iteration, the loop counter is incremented.

```plaintext
FOR i IN 1..3 LOOP  -- assign the values 1,2,3 to i
  sequence_of_statements;  -- executes three times
END LOOP;
```

The following example shows that if the lower bound equals the higher bound, the sequence of statements is executed once:

```plaintext
FOR i IN 3..3 LOOP  -- assign the value 3 to i
  sequence_of_statements;  -- executes one time
END LOOP;
```
By default, iteration proceeds upward from the lower bound to the higher bound. However, if you use the keyword REVERSE, iteration proceeds downward from the higher bound to the lower bound, as the example below shows. After each iteration, the loop counter is decremented.

```plsql
FOR i IN REVERSE 1..3 LOOP  -- assign the values 3,2,1 to i
    sequence_of_statements;  -- executes three times
END LOOP;
```

Nevertheless, you write the range bounds in ascending (not descending) order.

Inside a FOR loop, the loop counter can be referenced like a constant. So, the loop counter can appear in expressions but cannot be assigned values, as the following example shows:

```plsql
FOR ctr IN 1..10 LOOP
    ...
    IF NOT finished THEN
        INSERT INTO ... VALUES (ctr, ...);  -- legal
        factor := ctr * 2;  -- legal
    ELSE
        ctr := 10;  -- illegal
    END IF;
END LOOP;
```

The bounds of a loop range can be literals, variables, or expressions but must evaluate to integers. For example, the following iteration schemes are legal:

- `j IN -5..5`
- `k IN REVERSE first..last`
- `step IN 0..TRUNC(high/low) * 2`
- `code IN ASCII('A')..ASCII('J')`

As you can see, the lower bound need not be 1. However, the loop counter increment (or decrement) must be 1. Some languages provide a STEP clause, which lets you specify a different increment. An example written in BASIC follows:

```basic
FOR J = 5 TO 15 STEP 5  :REM assign values 5,10,15 to J
    sequence_of_statements  -- J has values 5,10,15
NEXT J
```
PL/SQL has no such structure, but you can easily build one. Consider the following example:

```plsql
FOR j IN 5..15 LOOP  -- assign values 5,6,7,... to j
    IF MOD(j, 5) = 0 THEN  -- pass multiples of 5
        sequence_of_statements;  -- j has values 5,10,15
    END IF;
END LOOP;
```

This loop is logically equivalent to the previous BASIC loop. Within the sequence of statements, the loop counter has only the values 5, 10, and 15.

You might prefer the less elegant but more efficient method shown in the example below. Within the sequence of statements, each reference to the loop counter is multiplied by the increment.

```plsql
FOR j IN 1..3 LOOP  -- assign values 1,2,3 to j
    sequence_of_statements;  -- each j becomes j*5
END LOOP;
```

PL/SQL lets you determine the loop range dynamically at run time, as the following example shows:

```plsql
SELECT COUNT(empno) INTO emp_count FROM emp;
FOR i IN 1..emp_count LOOP
    ...
END LOOP;
```

The value of `emp_count` is unknown at compile time; the SELECT statement returns the value at run time.

What happens if the lower bound of a loop range evaluates to a larger integer than the upper bound? As the following example shows, the sequence of statements within the loop is not executed and control passes to the next statement:

```plsql
-- limit becomes 1
FOR i IN 2..limit LOOP
    sequence_of_statements;  -- executes zero times
END LOOP;
-- control passes here
```

The loop counter is defined only within the loop. You cannot reference it outside the loop. After the loop is exited, the loop counter is undefined, as the following example shows:

```plsql
FOR ctr IN 1..10 LOOP
    ...
END LOOP;
sum := ctr - 1;  -- illegal
```
You need not explicitly declare the loop counter because it is implicitly declared as a local variable of type INTEGER. The next example shows that the local declaration hides any global declaration:

```
DECLARE
  ctr  INTEGER;
BEGIN
  ...
  FOR ctr IN 1..25 LOOP
    ...
    IF ctr > 10 THEN ... -- refers to loop counter
  END LOOP;
END;
```

To reference the global variable in this example, you must use a label and dot notation, as follows:

```
<<main>>
DECLARE
  ctr  INTEGER;
  ...
BEGIN
  ...
  FOR ctr IN 1..25 LOOP
    ...
    IF main.ctr > 10 THEN ... -- refers to global variable
  END LOOP;
END main;
```

The same scope rules apply to nested FOR loops. Consider the example below. Both loop counters have the same name. So, to reference the outer loop counter from the inner loop, you must use a label and dot notation, as follows:

```
<<outer>>
FOR step IN 1..25 LOOP
    FOR step IN 1..10 LOOP
        ...
        IF outer.step > 15 THEN ...
    END LOOP;
END LOOP outer;
```
Using the EXIT Statement

The EXIT statement allows a FOR loop to complete prematurely. For example, the following loop normally executes ten times, but as soon as the FETCH statement fails to return a row, the loop completes no matter how many times it has executed:

```
FOR j IN 1..10 LOOP
    FETCH c1 INTO emp_rec;
    EXIT WHEN c1%NOTFOUND;
    ...
END LOOP;
```

Suppose you must exit from a nested FOR loop prematurely. You can complete not only the current loop, but any enclosing loop. Simply label the enclosing loop that you want to complete. Then, use the label in an EXIT statement to specify which FOR loop to exit, as follows:

```
<<outer>>
FOR i IN 1..5 LOOP
    ...
    FOR j IN 1..10 LOOP
        FETCH c1 INTO emp_rec;
        EXIT outer WHEN c1%NOTFOUND; -- exit both FOR loops
        ...
    END LOOP;
END LOOP outer;
-- control passes here
```

Sequential Control: GOTO and NULL Statements

Unlike the IF and LOOP statements, the GOTO and NULL statements are not crucial to PL/SQL programming. The structure of PL/SQL is such that the GOTO statement is seldom needed. Occasionally, it can simplify logic enough to warrant its use. The NULL statement can make the meaning and action of conditional statements clear and so improve readability.
GOTO Statement

The GOTO statement branches to a label unconditionally. The label must be unique within its scope and must precede an executable statement or a PL/SQL block. When executed, the GOTO statement transfers control to the labeled statement or block. In the following example, you go to an executable statement farther down in a sequence of statements:

```
BEGIN
  ...
  GOTO insert_row;
  ...
<<insert_row>>
  INSERT INTO emp VALUES ...
END;
```

In the next example, you go to a PL/SQL block farther up in a sequence of statements:

```
BEGIN
  ...
  <<update_row>>
  BEGIN
    UPDATE emp SET ...
    ...
  END;
  ...
  GOTO update_row;
  ...
END;
```

The label <<end_loop>> in the following example is illegal because it does not precede an executable statement:

```
DECLARE
done BOOLEAN;
BEGIN
  ...
  FOR i IN 1..50 LOOP
    IF done THEN
      GOTO end_loop;
    END IF;
    ...
<<end_loop>>  -- illegal
  END LOOP;  -- not an executable statement
END;
```
To debug the last example, simply add the NULL statement, as follows:

```sql
DECLARE
  done  BOOLEAN;
BEGIN
  ...
  FOR i IN 1..50 LOOP
    IF done THEN
      GOTO end_loop;
    END IF;
    ...
  END LOOP;
END;
```

As the following example shows, a GOTO statement can branch to an enclosing block from the current block:

```sql
DECLARE
  my_ename  CHAR(10);
BEGIN
  ...
  GOTO update_row;  -- illegal branch into IF statement
  ...
  IF valid THEN
    ...
  END IF;
END;
```

Some possible destinations of a GOTO statement are illegal. Specifically, a GOTO statement cannot branch into an IF statement, LOOP statement, or sub-block. For example, the following GOTO statement is illegal:

```sql
BEGIN
  ...
  GOTO update_row;  -- illegal branch into IF statement
  ...
  IF valid THEN
    ...
  END IF;
END;
```
Also, a GOTO statement cannot branch from one IF statement clause to another, as the following example shows:

```
BEGIN
  ...
  IF valid THEN
    ...
    GOTO update_row;  -- illegal branch into ELSE clause
  ELSE
    ...
    <<update_row>>
    UPDATE emp SET ...
  END IF;
END;
```

The next example shows that a GOTO statement cannot branch from an enclosing block into a sub-block:

```
BEGIN
  ...
  IF status = 'OBSOLETE' THEN
    GOTO delete_part;  -- illegal branch into sub-block
  END IF;
  ...
  BEGIN
    ...
    <<delete_part>>
    DELETE FROM parts WHERE ...
  END;
END;
```

Also, a GOTO statement cannot branch out of a subprogram, as the following example shows:

```
DECLARE
  ...
  PROCEDURE compute_bonus (emp_id NUMBER) IS
    BEGIN
      ...
      GOTO update_row;  -- illegal branch out of subprogram
    END;
    BEGIN
      ...
      <<update_row>>
      UPDATE emp SET ...
    END;
```
Finally, a GOTO statement cannot branch from an exception handler into the current block. For example, the following GOTO statement is illegal:

```
DECLARE
...
  pe_ratio  REAL;
BEGIN
...
  SELECT price / NVL(earnings, 0) INTO pe_ratio FROM ...<<insert_row>>
  INSERT INTO stats VALUES (pe_ratio, ...);
EXCEPTION
  WHEN ZERO_DIVIDE THEN
    pe_ratio := 0;
    GOTO insert_row;  -- illegal branch into current block
...
END;
```

However, a GOTO statement can branch from an exception handler into an enclosing block.

Guidelines

Overuse of GOTO statements can result in complex, unstructured code (sometimes called spaghetti code) that is hard to understand and maintain. So, use GOTO statements sparingly. For example, to branch from a deeply nested structure to an error-handling routine, raise an exception rather than use a GOTO statement.

NULL Statement

The NULL statement explicitly specifies inaction; it does nothing other than pass control to the next statement. It can, however, improve readability. In a construct allowing alternative actions, the NULL statement serves as a placeholder. It tells readers that the associated alternative has not been overlooked, but that indeed no action is necessary. In the following example, the NULL statement shows that no action is taken for unnamed exceptions:

```
EXCEPTION
  WHEN ZERO_DIVIDE THEN
    ROLLBACK;
  WHEN VALUE_ERROR THEN
    INSERT INTO errors VALUES ...
    COMMIT;
  WHEN OTHERS THEN
    NULL;
END;
```
Each clause in an IF statement must contain at least one executable statement. The NULL statement meets this requirement. So, you can use the NULL statement in clauses that correspond to circumstances in which no action is taken. In the following example, the NULL statement emphasizes that only top-rated employees receive bonuses:

```sql
IF rating > 90 THEN
    compute_bonus(emp_id);
ELSE
    NULL;
END IF;
```

Also, the NULL statement is a handy way to create stubs when designing applications from the top down. A stub is dummy subprogram that allows you to defer the definition of a procedure or function until you test and debug the main program. In the following example, the NULL statement meets the requirement that at least one statement must appear in the executable part of a subprogram:

```sql
PROCEDURE debit_account (acct_id INTEGER, amount REAL) IS
BEGIN
    NULL;
END debit_account;
```
Knowledge is of two kinds. We know a subject ourselves, or we know where we can find information upon it.

Samuel Johnson

This chapter helps you harness the power of Oracle. You learn how PL/SQL supports the SQL commands, functions, and operators that let you manipulate Oracle data. You also learn how to manage cursors, process transactions, and safeguard the consistency of your database.
SQL Support

By extending SQL, PL/SQL offers a unique combination of power and ease of use. You can manipulate Oracle data flexibly and safely because PL/SQL supports all SQL data manipulation commands (except EXPLAIN PLAN), transaction control commands, functions, pseudocolumns, and operators. Also, PL/SQL conforms to SQL92, the current ANSI/ISO SQL standard.

Note: PL/SQL does not support data definition commands such as ALTER and CREATE. For an explanation and workaround, see “Using DDL and Dynamic SQL” on page 4 – 8.

Data Manipulation

To manipulate Oracle data, you use the INSERT, UPDATE, DELETE, SELECT, and LOCK TABLE commands. INSERT adds new rows of data to database tables; UPDATE modifies rows; DELETE removes unwanted rows; SELECT retrieves rows that meet your search criteria; and LOCK TABLE temporarily limits access to a table.

Transaction Control

Oracle is transaction oriented; that is, Oracle uses transactions to ensure data integrity. A transaction is a series of SQL data manipulation statements that does a logical unit of work. For example, two UPDATE statements might credit one bank account and debit another.

Simultaneously, Oracle makes permanent or undoes all database changes made by a transaction. If your program fails in the middle of a transaction, Oracle detects the error and rolls back the transaction. Thus, the database is restored to its former state automatically.

You use the COMMIT, ROLLBACK, SAVEPOINT, and SET TRANSACTION commands to control transactions. COMMIT makes permanent any database changes made during the current transaction. ROLLBACK ends the current transaction and undoes any changes made since the transaction began. SAVEPOINT marks the current point in the processing of a transaction. Used with ROLLBACK, SAVEPOINT undoes part of a transaction. SET TRANSACTION establishes a read–only transaction.

SQL Functions

PL/SQL lets you use all the SQL functions including the following group functions, which summarize entire columns of Oracle data: AVG, COUNT, MAX, MIN, STDDEV, SUM, and VARIANCE.

The group functions GLB and LUB are available only with Trusted Oracle. GLB and LUB return the greatest lower bound and least upper bound of an operating system label, respectively. For more information, see Trusted Oracle7 Server Administrator’s Guide, Release 7.1.
You can use the group functions in SQL statements, but not in procedural statements. Group functions operate on entire columns unless you use the SELECT GROUP BY statement to sort returned rows into subgroups. If you omit the GROUP BY clause, the group function treats all returned rows as a single group.

You call a group function using the syntax

```
function_name([ALL | DISTINCT] expr)
```

where `expr` is an expression that refers to one or more database columns. If you specify the ALL option (the default), the group function considers all column values including duplicates. For example, the following statement returns the sample standard deviation ($s$) of all values in the `comm` column:

```
SELECT STDDEV(comm) INTO comm_sigma FROM emp;
```

If you specify the DISTINCT option, the group function considers only distinct values. For example, the following statement returns the number of different job titles in the `emp` table:

```
SELECT COUNT(DISTINCT job) INTO job_count FROM emp;
```

The `COUNT` function lets you specify the asterisk (*) option, which returns the number of rows in a table. For example, the following statement returns the number of employees in the `emp` table:

```
SELECT COUNT(*) INTO emp_count FROM emp;
```

Except for `COUNT(*)`, all group functions ignore nulls.

### SQL Pseudocolumns

PL/SQL recognizes the following SQL pseudocolumns, which return specific data items: `CURRVAL`, `LEVEL`, `NEXTVAL`, `ROWID`, and `ROWNUM`.

Pseudocolumns are not actual columns in a table but they behave like columns. For example, you can select values from a pseudocolumn. However, you cannot insert values into, update values in, or delete values from a pseudocolumn.

You can use pseudocolumns in SQL statements, but not in procedural statements. In the following example, you use the database sequence `empno_seq` and the pseudocolumn `NEXTVAL` (which returns the next value in a database sequence) to insert a new employee number into the `emp` table:

```
INSERT INTO emp VALUES ( empno_seq.NEXTVAL, new_ename, ... );
```
Brief descriptions of the pseudocolumns follow. For more information, see Oracle7 Server SQL Reference.

**CURRVAL and NEXTVAL**  
A *sequence* is a database object that generates sequential numbers. When you create a sequence, you can specify its initial value and an increment.

CURRVAL returns the current value in a specified sequence. Before you can reference CURRVAL in a session, you must use NEXTVAL to generate a number. A reference to NEXTVAL stores the current sequence number in CURRVAL. NEXTVAL increments the sequence and returns the next value. To obtain the current or next value in a sequence, you must use dot notation, as follows:

```
sequence_name.CURRVAL
sequence_name.NEXTVAL
```

After creating a sequence, you can use it to generate unique sequence numbers for transaction processing. However, you can use CURRVAL and NEXTVAL only in a select list, the VALUES clause, and the SET clause. In the following example, you use a sequence to insert the same employee number into two tables:

```
INSERT INTO emp VALUES (empno_seq.NEXTVAL, my_ename, ...);
INSERT INTO sals VALUES (empno_seq.CURRVAL, my_sal, ...);
```

If a transaction generates a sequence number, the sequence is incremented immediately whether you commit or roll back the transaction.

**LEVEL**  
You use LEVEL with the SELECT CONNECT BY statement to organize rows from a database table into a tree structure. LEVEL returns the level number of a node in a tree structure. The root is level 1, children of the root are level 2, grandchildren are level 3, and so on.

You specify the direction in which the query walks the tree (down from the root or up from the branches) with the PRIOR operator. In the START WITH clause, you specify a condition that identifies the root of the tree.

**ROWID**  
ROWID returns the rowid (binary address) of a row in a database table. Recall that PL/SQL provides a datatype also named ROWID. You can use variables of type ROWID to store rowids in a readable format. In the following example, you declare a variable named `row_id` for that purpose:

```
DECLARE
    row_id ROWID;
```
When you select or fetch a rowid into a ROWID variable, you can use the function ROWIDTOCHAR, which converts the binary value to an 18-byte character string. Then, you can compare the ROWID variable to the ROWID pseudocolumn in the WHERE clause of an UPDATE or DELETE statement to identify the latest row fetched from a cursor. For an example, see “Fetching Across Commits” on page 4–43.

**ROUNUM**

ROUNUM returns a number indicating the order in which a row was selected from a table. The first row selected has a ROWNUM of 1, the second row has a ROWNUM of 2, and so on. If a SELECT statement includes an ORDER BY clause, ROWNUMs are assigned to the retrieved rows before the sort is done.

You can use ROWNUM in an UPDATE statement to assign unique values to each row in a table. Also, you can use ROWNUM in the WHERE clause of a SELECT statement to limit the number of rows retrieved, as follows:

```plsql
DECLARE
    CURSOR c1 IS SELECT empno, sal FROM emp
        WHERE sal > 2000 AND ROWNUM < 10;  -- returns 10 rows

The value of ROWNUM increases only when a row is retrieved, so the only meaningful use of ROWNUM in a WHERE clause is

... WHERE ROWNUM < constant;
```

For example, the following condition cannot be met because the first nine rows are never retrieved:

```plsql
... WHERE ROWNUM = 10;
```

**ROWLABEL Column**

PL/SQL also recognizes the special column ROWLABEL, which Trusted Oracle creates for every database table. Like other columns, ROWLABEL can be referenced in SQL statements. However, with standard Oracle, ROWLABEL returns a null. With Trusted Oracle, ROWLABEL returns the operating system label for a row.

A common use of ROWLABEL is to filter query results. For example, the following statement counts only those rows with a security level higher than “unclassified”:

```sql
SELECT COUNT(*) INTO head_count FROM emp
    WHERE ROWLABEL > 'UNCLASSIFIED';
```
PL/SQL lets you use all the SQL comparison, set, and row operators in SQL statements. This section briefly describes some of these operators. For more information, see Oracle7 Server SQL Reference.

**Comparison Operators**

 Typically, you use comparison operators in the WHERE clause of a data manipulation statement to form *predicates*, which compare one expression to another and always yields TRUE, FALSE, or NULL. You can use all the comparison operators listed below to form predicates. Moreover, you can combine predicates using the logical operators AND, OR, and NOT.

- **ALL**
  Compares a value to each value in a list or returned by a subquery and yields TRUE if all of the individual comparisons yield TRUE.

- **ANY, SOME**
  Compares a value to each value in a list or returned by a subquery and yields TRUE if any of the individual comparisons yields TRUE.

- **BETWEEN**
  Tests whether a value lies in a specified range.

- **EXISTS**
  Returns TRUE if a subquery returns at least one row.

- **IN**
  Tests for set membership.

- **IS NULL**
  Tests for nulls.

- **LIKE**
  Tests whether a character string matches a specified pattern, which can include wildcards.

**Set Operators**

Set operators combine the results of two queries into one result. INTERSECT returns all distinct rows selected by both queries. MINUS returns all distinct rows selected by the first query but not by the second. UNION returns all distinct rows selected by either query. UNION ALL returns all rows selected by either query, including all duplicates.

**Row Operators**

Row operators return or reference particular rows. ALL retains duplicate rows in the result of a query or in an aggregate expression. DISTINCT eliminates duplicate rows from the result of a query or from an aggregate expression. PRIOR refers to the parent row of the current row returned by a tree–structured query. You must use this operator in the CONNECT BY clause of such a query to define the parent–child relationship.
In late 1992, the American National Standards Institute (ANSI) and the International Organization for Standardization (ISO) adopted the current SQL standard known informally as SQL92, which greatly extends the previous SQL standard (SQL89).

Note: SQL92 is known officially as International Standard ISO/IEC 9075:1992, Database Language SQL, which is also available as ANSI Document ANSI X3.135–1992.

SQL92 specifies a “conforming SQL language” and, to allow implementation in stages, defines three language levels:

- Full SQL
- Intermediate SQL (a subset of Full SQL)
- Entry SQL (a subset of Intermediate SQL)

A conforming SQL implementation must support at least Entry SQL. PL/SQL achieves full support for Entry SQL by letting you

- reference column aliases in the ORDER BY clause
- use the keyword AS to introduce aliases in the SELECT clause

Conceptually, the rows returned by a multi-row SELECT statement form a result table. Like the rows in a database table, the rows in a result table are not arranged in any particular order. However, you can use the ORDER BY clause to sort the rows in a result table by one or more columns.

Previously, if you wanted to sort the rows in a result table by a calculated (and therefore nameless) column, you had to specify the corresponding select-item or its ordinal position. In the following example, the number 3 denotes the calculated column sal+comm, which is the third select-item:

```sql
DECLARE
  CURSOR c1 IS
    SELECT empno, ename, sal+comm
    FROM emp
    WHERE job = 'SALESPERSON'
    ORDER BY 3;  -- or ORDER BY sal+comm
```

However, under SQL92, this method is a “deprecated feature” retained only for compatibility with SQL89 and likely to be removed from future versions of the standard.
Now a less error–prone method that ensures compliance with future SQL standards is available. You can specify a column alias for use in the ORDER BY clause. In the following example, the alias wages denotes the calculated column \( \text{sal+comm} \):

```sql
DECLARE
    CURSOR c1 IS
        SELECT empno, ename, sal+comm wages
        FROM emp
        WHERE job = 'SALESPERSON'
        ORDER BY wages;
```

Furthermore, you can use the optional keyword AS in the SELECT clause to improve readability, as follows:

```sql
DECLARE
    CURSOR c1 IS
        SELECT empno, ename, sal+comm AS wages
        FROM emp
        WHERE job = 'SALESPERSON'
        ORDER BY wages;
```

---

### Using DDL and Dynamic SQL

This section explains why PL/SQL does not support SQL data definition language (DDL) or dynamic SQL, then shows how to solve the problem.

#### Efficiency versus Flexibility

Before a PL/SQL program can be executed, it must be compiled. The PL/SQL compiler resolves references to Oracle objects by looking up their definitions in the data dictionary. Then, the compiler assigns storage addresses to program variables that will hold Oracle data so that Oracle can look up the addresses at run time. This process is called *binding*.

How a database language implements binding affects runtime efficiency and flexibility. Binding at compile time, called *static or early binding*, increases efficiency because the definitions of database objects are looked up then, not at run time. On the other hand, binding at run time, called *dynamic or late binding*, increases flexibility because the definitions of database objects can remain unknown until then.

Designed primarily for high–speed transaction processing, PL/SQL increases efficiency by bundling SQL statements and avoiding runtime compilation. Unlike SQL, which is compiled and executed statement–by–statement at run time (late binding), PL/SQL is processed into machine–readable p–code at compile time (early binding). At run time, the PL/SQL engine simply executes the p–code.
Some Limitations

However, this design imposes some limitations. For example, the p-code includes references to database objects such as tables and stored procedures. The PL/SQL compiler can resolve such references only if the database objects are known at compile time. In the following example, the compiler cannot process the procedure because the table is undefined until the procedure is executed at run time:

```sql
CREATE PROCEDURE create_table AS
    BEGIN
        CREATE TABLE dept (deptno NUMBER(2), ...);   -- illegal
    END;
```

In the next example, the compiler cannot bind the table reference in the DROP TABLE statement because the table name is unknown until the procedure is executed:

```sql
CREATE PROCEDURE drop_table (table_name IN VARCHAR2) AS
    BEGIN
        DROP TABLE table_name;   -- illegal
    END;
```

Overcoming the Limitations

However, the package DBMS_SQL, which is supplied with Oracle7, allows PL/SQL to execute SQL data definition and data manipulation statements dynamically at run time. For example, when called, the following stored procedure drops a specified database table:

```sql
CREATE PROCEDURE drop_table (table_name IN VARCHAR2) AS
    cid INTEGER;
    BEGIN
        /* Open new cursor and return cursor ID. */
        cid := dbms_sql.open_cursor;
        /* Parse and immediately execute dynamic SQL statement built by concatenating table name to DROP TABLE command. */
        dbms_sql.parse(cid, 'DROP TABLE ' || table_name, dbms_sql.v7);
        /* Close cursor. */
        dbms_sql.close_cursor(cid);
    EXCEPTION
        /* If an exception is raised, close cursor before exiting. */
        WHEN OTHERS THEN
            dbms_sql.close_cursor(cid);
            RAISE;   -- reraise the exception
    END;
```

For more information about package DBMS_SQL, see Oracle7 Server Application Developer’s Guide.
Managing Cursors

Recall from Chapter 1 that PL/SQL uses two types of cursors: implicit and explicit. PL/SQL declares a cursor implicitly for all SQL data manipulation statements, including queries that return only one row. However, for queries that return more than one row, you must declare an explicit cursor or use a cursor FOR loop.

Explicit Cursors

The set of rows returned by a query can consist of zero, one, or multiple rows, depending on how many rows meet your search criteria. When a query returns multiple rows, you can explicitly declare a cursor to process the rows. You can declare a cursor in the declarative part of any PL/SQL block, subprogram, or package.

You use three commands to control a cursor: OPEN, FETCH, and CLOSE. First, you initialize the cursor with the OPEN statement, which identifies the active set. Then, you use the FETCH statement to retrieve the first row. You can execute FETCH repeatedly until all rows have been retrieved. When the last row has been processed, you release the cursor with the CLOSE statement. You can process several queries in parallel by declaring and opening multiple cursors.

Declaring a Cursor

Forward references are not allowed in PL/SQL. So, you must declare a cursor before referencing it in other statements. When you declare a cursor, you name it and associate it with a specific query. In the following example, you declare a cursor named c1:

```sql
DECLARE
    CURSOR c1 IS SELECT ename, deptno FROM emp WHERE sal > 2000;
END;
```

The cursor name is an undeclared identifier, not the name of a PL/SQL variable. You cannot assign values to a cursor name or use it in an expression. However, cursors and variables follow the same scoping rules. Naming cursors after database tables is allowed but not recommended.

A cursor can take parameters, which can appear in the associated query wherever constants can appear. To declare formal cursor parameters, you use the syntax

```sql
CURSOR cursor_name [(parameter [, parameter, ...])] IS SELECT ...
```

where `parameter` stands for the following syntax:

```sql
parameter_name [IN] datatype [{:= | DEFAULT} expr]
```

The formal parameters of a cursor must be IN parameters. Therefore, they cannot return values to actual parameters. (For more information, see “Parameter Modes” on page 6–15.)
As the example below shows, you can initialize cursor parameters to default values. That way, you can pass different numbers of actual parameters to a cursor, accepting or overriding the default values as you please. Also, you can add new formal parameters without having to change every reference to the cursor.

```
DECLARE
    CURSOR c1 (low INTEGER DEFAULT 0,
                high INTEGER DEFAULT 99) IS SELECT ... 

The scope of cursor parameters is local to the cursor, meaning that they can be referenced only within the query specified in the cursor declaration. The values of cursor parameters are used by the associated query when the cursor is opened.
```

Opening a Cursor

Opening the cursor executes the query and identifies the active set, which consists of all rows that meet the query search criteria. For cursors declared using the FOR UPDATE clause, the OPEN statement also locks those rows. An example of the OPEN statement follows:

```
DECLARE
    CURSOR c1 IS SELECT ename, job FROM emp WHERE sal < 3000;
    ... 
BEGIN
    OPEN c1;

Rows in the active set are not retrieved when the OPEN statement is executed. Rather, the FETCH statement retrieves the rows.

Passing Parameters

You use the OPEN statement to pass parameters to a cursor. Unless you want to accept default values, each formal parameter in the cursor declaration must have a corresponding actual parameter in the OPEN statement. For example, given the cursor declaration

```
DECLARE
    emp_name emp.ename%TYPE;
    salary   emp.sal%TYPE;
    CURSOR c1 (name VARCHAR2, salary NUMBER) IS SELECT ... 
```

any of the following statements opens the cursor:

```
OPEN c1(emp_name, 3000);
OPEN c1(‘ATTLEY’, 1500);
OPEN c1(emp_name, salary);
```

In the last example, when the identifier salary is used in the cursor declaration, it refers to the formal parameter. But, when it is used in the OPEN statement, it refers to the PL/SQL variable. To avoid confusion, use unique identifiers.
Formal parameters declared with a default value need not have a corresponding actual parameter. They can simply assume their default values when the OPEN statement is executed.

You can associate the actual parameters in an OPEN statement with the formal parameters in a cursor declaration using positional or named notation. (See “Positional and Named Notation” on page 6–12.) The datatypes of each actual parameter and its corresponding formal parameter must be compatible.

The FETCH statement retrieves the rows in the active set one at a time. After each fetch, the cursor advances to the next row in the active set. An example of the FETCH statement follows:

```
FETCH c1 INTO my_empno, my_ename, my_deptno;
```

For each column value returned by the query associated with the cursor, there must be a corresponding variable in the INTO list. Also, their datatypes must be compatible. Typically, you use the FETCH statement as follows:

```
OPEN c1;
LOOP
  FETCH c1 INTO my_record;
  EXIT WHEN c1%NOTFOUND;
  -- process data record
END LOOP;
```

The query can reference PL/SQL variables within its scope. However, any variables in the query are evaluated only when the cursor is opened. In the following example, each retrieved salary is multiplied by 2, even though factor is incremented after each fetch:

```
DECLARE
  my_sal emp.sal%TYPE;
  my_job emp.job%TYPE;
  factor INTEGER := 2;
  CURSOR c1 IS SELECT factor*sal FROM emp WHERE job = my_job;
BEGIN
  ...
  OPEN c1;  -- here factor equals 2
  LOOP
    FETCH c1 INTO my_sal;
    EXIT WHEN c1%NOTFOUND;
    ...  
    factor := factor + 1;  -- does not affect FETCH
  END LOOP;
END;
```
To change the active set or the values of variables in the query, you must close and reopen the cursor with the input variables set to their new values.

However, you can use a different INTO list on separate fetches with the same cursor. Each fetch retrieves another row and assigns values to the target variables, as the following example shows:

```sql
DECLARE
    CURSOR c1 IS SELECT ename FROM emp;
    name1 emp.ename%TYPE;
    name2 emp.ename%TYPE;
    name3 emp.ename%TYPE;
BEGIN
    OPEN c1;
    FETCH c1 INTO name1;  -- this fetches first row
    FETCH c1 INTO name2;  -- this fetches second row
    FETCH c1 INTO name3;  -- this fetches third row
    ...  
    CLOSE c1;
END;
```

**Important Points**

If you fetch past the last row in the active set, the values of the target variables are indeterminate.

Eventually, the FETCH statement must fail to return a row; so when that happens, no exception is raised. In fact, the FETCH statement can fail repeatedly without raising an exception. So, whenever you place a FETCH statement inside a basic loop, include an EXIT WHEN statement. Otherwise, you have an infinite loop.

**Closing a Cursor**

The CLOSE statement disables the cursor, and the active set becomes undefined. An example of the CLOSE statement follows:

```sql
CLOSE c1;
```

Once a cursor is closed, you can reopen it. Any other operation on a closed cursor raises the predefined exception INVALID_CURSOR.

**Implicit Cursors**

Oracle implicitly opens a cursor to process each SQL statement not associated with an explicitly declared cursor. PL/SQL lets you refer to the most recent implicit cursor as the “SQL” cursor.

You cannot use the OPEN, FETCH, and CLOSE statements to control the SQL cursor. But, you can use cursor attributes to get information about the most recently executed SQL statement. See “Using Cursor Attributes” on page 4 – 29.
Packaging Cursors

You can separate a cursor specification from its body for placement in a package. That way, you can change the cursor body without having to change the cursor specification. You code the cursor specification in the package specification using the syntax:

```plsql
CURSOR cursor_name RETURN return_type;
```

where `return_type` stands for the following syntax:

- `record_type`
- `record_variable%TYPE`
- `cursor%ROWTYPE`
- `table%ROWTYPE`

Notice that the return type must be a record type. In the following example, you use the `%ROWTYPE` attribute to provide a record type that represents a row in the `emp` table:

```plsql
CREATE PACKAGE emp_actions AS
  /* Declare cursor specification. */
  CURSOR c1 RETURN emp%ROWTYPE;
  ...
END emp_actions;
```

```plsql
CREATE PACKAGE BODY emp_actions AS
  /* Define cursor body. */
  CURSOR c1 RETURN emp%ROWTYPE
      SELECT * FROM emp WHERE sal > 3000;
  ...
END emp_actions;
```

The cursor specification has no SELECT statement because the RETURN clause defines the datatype of the result value. However, the cursor body must have a SELECT statement and the same RETURN clause as its corresponding cursor specification. Also, the number and datatypes of select–list items in the SELECT statement must match the RETURN clause.

Packaged cursors increase flexibility. For instance, you can change the cursor body in the last example, as follows, without having to change the cursor specification:

```plsql
CREATE PACKAGE BODY emp_actions AS
  /* Define cursor body. */
  CURSOR c1 RETURN emp%ROWTYPE
      SELECT * FROM emp WHERE deptno = 20;  -- new WHERE clause
  ...
END emp_actions;
```
Using Cursor FOR Loops

In most situations that require an explicit cursor, you can simplify coding by using a cursor FOR loop instead of the OPEN, FETCH, and CLOSE statements. A cursor FOR loop implicitly declares its loop index as a %ROWTYPE record, opens a cursor, repeatedly fetches rows of values from the active set into fields in the record, and closes the cursor when all rows have been processed.

Consider the PL/SQL block below, which computes results from an experiment, then stores the results in a temporary table. The FOR loop index \texttt{c1rec} is implicitly declared as a record. Its fields store all the column values fetched from the cursor \texttt{c1}. Dot notation is used to reference individual fields.

\texttt{-- available online in file EXAMP7}
\begin{verbatim}
DECLARE
    result temp.col1%TYPE;
    CURSOR c1 IS
        SELECT n1, n2, n3 FROM data_table WHERE exper_num = 1;
BEGIN
    FOR c1rec IN c1 LOOP
        /* calculate and store the results */
        result := c1rec.n2 / (c1rec.n1 + c1rec.n3);
        INSERT INTO temp VALUES (result, NULL, NULL);
    END LOOP;
    COMMIT;
END;
\end{verbatim}

When the cursor FOR loop is entered, the cursor name cannot belong to a cursor that was already opened by an OPEN statement or by an enclosing cursor FOR loop. Before each iteration of the FOR loop, PL/SQL fetches into the implicitly declared record, which is equivalent to a record explicitly declared as follows:

\texttt{c1rec c1%ROWTYPE;}

The record is defined only inside the loop. You cannot refer to its fields outside the loop. For example, the following reference is illegal:

\texttt{FOR c1rec IN c1 LOOP}
\begin{verbatim}
    ...
    END LOOP;
    result := c1rec.n2 + 3;  -- illegal
\end{verbatim}

The sequence of statements inside the loop is executed once for each row that satisfies the query associated with the cursor. When you leave the loop, the cursor is closed automatically. This is true even if you use an EXIT or GOTO statement to leave the loop prematurely or if an exception is raised inside the loop.
Using Aliases

Fields in the implicitly declared record hold column values from the most recently fetched row. The fields have the same names as corresponding columns in the query select list. But, what happens if a select-item is an expression? Consider the following example:

```sql
CURSOR c1 IS
    SELECT empno, sal+NVL(comm,0), job FROM ...
```

In such cases, you must include an alias for the select-item. In the next example, `wages` is an alias for the select-item `sal+NVL(comm,0):

```sql
CURSOR c1 IS
    SELECT empno, sal+NVL(comm,0) wages, job FROM ...
```

To reference the corresponding field, you use the alias instead of a column name, as follows:

```sql
IF emp_rec.wages < 1000 THEN ...
```

Passing Parameters

You can pass parameters to the cursor used in a cursor FOR loop. In the following example, you pass a department number. Then, you compute the total wages paid to employees in that department. Also, you determine how many employees have salaries higher than $2000 and how many have commissions larger than their salaries.

```sql
-- available online in file EXAMP8
DECLARE
    CURSOR emp_cursor(dnum NUMBER) IS
        SELECT sal, comm FROM emp WHERE deptno = dnum;
    total_wages NUMBER(11,2) := 0;
    high_paid NUMBER(4) := 0;
    higher_comm NUMBER(4) := 0;
BEGIN
    /* The number of iterations will equal the number of rows *
    * returned by emp_cursor. */
    FOR emp_record IN emp_cursor(20) LOOP
        emp_record.comm := NVL(emp_record.comm, 0);
        total_wages := total_wages + emp_record.sal +
                        emp_record.comm;
        IF emp_record.sal > 2000.00 THEN
            high_paid := high_paid + 1;
        END IF;
        IF emp_record.comm > emp_record.sal THEN
            higher_comm := higher_comm + 1;
        END IF;
    END LOOP;
    INSERT INTO temp VALUES (high_paid, higher_comm,
                'Total Wages: ' || TO_CHAR(total_wages));
    COMMIT;
END;
```
Using Cursor Variables

Like a cursor, a cursor variable points to the current row in the active set of a multi-row query. But, cursors differ from cursor variables the way constants differ from variables. Whereas a cursor is static, a cursor variable is dynamic because it is not tied to a specific query. You can open a cursor variable for any type-compatible query. This gives you more flexibility.

Also, you can assign new values to a cursor variable and pass it as a parameter to subprograms, including subprograms stored in an Oracle database. This gives you an easy way to centralize data retrieval.

The Basic Procedure

You must declare and initialize a cursor variable in a PL/SQL host environment such as a Pro*C, OCI, or SQL*Module program. To use the host cursor variable, you must pass it as a bind variable to PL/SQL, open it on the server side, then fetch from it back on the client side. Consider the following (simplified) Pro*C example:

```sql
EXEC SQL BEGIN DECLARE SECTION;
...
/* Declare cursor variable. */
SQL_CURSOR emp_cv;
/* Declare record to hold fetched row. */
struct { ... } emp_rec;
EXEC SQL END DECLARE SECTION;
...
/* Initialize cursor variable. */
EXEC SQL ALLOCATE :emp_cv;
...
EXEC SQL EXECUTE
/* Pass cursor variable to PL/SQL block. */
BEGIN
/* Open cursor variable. */
OPEN :emp_cv FOR SELECT * FROM emp;
/* bind variables must be prefixed with a colon.END;
END-EXEC;
...
for (;;) {
/* Fetch row into record. */
EXEC SQL FETCH :emp_cv INTO emp_rec;
...
}
```
In the next example, you open the host cursor variable by passing it to a local PL/SQL procedure, which declares a PL/SQL cursor variable as its formal parameter:

```sql
EXEC SQL EXECUTE
DECLARE
    TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
    PROCEDURE open_emp_cv (cv IN OUT EmpCurTyp) IS
        BEGIN
            OPEN cv FOR SELECT * FROM emp;
        END;
    BEGIN
        open_emp_cv(:emp_cv);  -- call local procedure
    END;
END-EXEC;
```

The following discussion focuses on PL/SQL cursor variables. For details about host cursor variables, see your Oracle tool user’s guide.

**What Are Cursor Variables?**

PL/SQL cursor variables are like C or Pascal pointers, which hold the memory location (address) of some object instead of the object itself. To execute a multi-row query, Oracle opens an unnamed work area that stores processing information. To access the information, you can use an explicit cursor, which names the work area. Or, you can use a cursor variable, which points to the work area.

In PL/SQL, pointers have datatype REF X, where REF is short for REFERENCE and X stands for a class of objects. Therefore, cursor variables have datatype REF CURSOR. Currently, cursor variables are the only REF variables that you can declare.

**Declaring Cursor Variables**

You must declare a PL/SQL cursor variable in two steps. First, you define a REF CURSOR type, then declare a cursor variable of that type. You can define REF CURSOR types in any PL/SQL block, subprogram, or package. However, you can declare cursor variables only in a block or subprogram. To define a REF CURSOR type, you use the syntax

```
TYPE type_name IS REF CURSOR RETURN return_type;
```

where `type_name` is a type specifier used in subsequent declarations of cursor variables and `return_type` stands for the following syntax:

```
{  record_type
 | record_variable%TYPE
 | cursor%ROWTYPE
 | cursor_variable%ROWTYPE
 | table%ROWTYPE }
```

Notice that `return_type` must be a record type. A host cursor variable is compatible with all of these record types.
Once you define a REF CURSOR type, you can declare cursor variables of that type. In the following example, you declare a cursor variable named \texttt{emp\_cv}:

```plsql
DECLARE
  TYPE EmpCurTyp IS REF CURSOR RETURN emp\%ROWTYPE;
  emp_cv EmpCurTyp;
END;
```

Cursor variables follow the usual scoping and instantiation rules. When you declare a cursor variable as the formal parameter of a procedure, specify the IN OUT mode. That way, the procedure can return an open cursor to the caller. (Specifying the IN mode will be useful in future releases of PL/SQL, which will let you pass an open cursor to subprograms so that they can fetch from it.)

In the example below, you define a REF CURSOR type named \texttt{EmpCurTyp}, then declare a cursor variable of that type as the formal parameter of a procedure. In the type definition, you use \%ROWTYPE to specify a record type that represents a row in the \texttt{emp} database table.

```plsql
DECLARE
  TYPE EmpCurTyp IS REF CURSOR RETURN emp\%ROWTYPE;
  PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp) IS ...
END;
```

You can also use \%ROWTYPE to specify a record type that represents a row returned by a (previously declared) cursor variable, as follows:

```plsql
DECLARE
  TYPE EmpCurTyp IS REF CURSOR RETURN emp\%ROWTYPE;
  tmp_cv TmpCurTyp;  -- declare cursor variable
  TYPE EmpCurTyp IS REF CURSOR RETURN tmp_cv\%ROWTYPE;
END;
```

Likewise, you can use \%TYPE to provide the datatype of a record variable, as the following example shows:

```plsql
DECLARE
  dept_rec dept\%ROWTYPE;  -- declare record variable
  TYPE DeptCurTyp IS REF CURSOR RETURN dept_rec\%TYPE;
END;
```

In the final example, you use a RECORD type to specify the return type of a cursor variable:

```plsql
DECLARE
  TYPE EmpRecTyp IS RECORD (  
    empno NUMBER(4),
    ename VARCHAR2(10),
    sal NUMBER(7,2));
  TYPE EmpCurTyp IS REF CURSOR RETURN EmpRecTyp;
END;
```
Controlling Cursor Variables

You use three statements to control a cursor variable: OPEN–FOR, FETCH, and CLOSE. First, you OPEN a cursor variable FOR a multi-row query on the server side, FETCH from it on the client side, then CLOSE it on either side.

Opening a Cursor Variable

You use the OPEN–FOR statement to associate a cursor variable with a multi-row query to execute the query and identify the active set. The syntax follows:

```sql
OPEN cursor_variable_name FOR select_statement;
```

Unlike cursors, cursor variables do not take parameters. No flexibility is lost, however, because you can pass whole queries (not just parameters) to a cursor variable. The query can reference bind variables and PL/SQL variables, parameters, and functions but cannot be FOR UPDATE. In the following example, you open a cursor variable named `emp_cv`:

```sql
OPEN emp_cv FOR SELECT * FROM emp;
```

Other OPEN–FOR statements can open the same cursor variable for different queries. You need not close a cursor variable before opening it again. (Recall that consecutive OPENs of a static cursor raise the predefined exception CURSOR_ALREADY_OPEN.)

You must open a cursor variable on the server side. You do that by passing it as a bind variable to an anonymous PL/SQL block. At run time, the block is sent to the Oracle Server for execution. In the following Pro*C example, you declare and initialize a host cursor variable named `emp_cv`, then pass it to a PL/SQL block, which opens the cursor variable:

```sql
EXEC SQL BEGIN DECLARE SECTION;
...
/* Declare cursor variable. */
SQL_CURSOR emp_cv;
EXEC SQL END DECLARE SECTION;
...
/* Initialize cursor variable. */
EXEC SQL ALLOCATE :emp_cv;
...
EXEC SQL EXECUTE
/* Pass cursor variable to PL/SQL block. */
BEGIN
 /* Open cursor variable. */
  OPEN :emp_cv FOR SELECT * FROM emp;
END;
END-EXEC;
```
For more flexibility, you can pass a host cursor variable and selector to a PL/SQL block that executes queries with different return types. (In this context, a selector is a variable used to select one of several alternatives in a conditional control statement.) As the following Pro*C example shows, a host cursor variable is compatible with any query return type:

```sql
EXEC SQL BEGIN DECLARE SECTION;
...
SQL_CURSOR generic_cv;
int choice;
EXEC SQL END DECLARE SECTION;
...
EXEC SQL ALLOCATE :generic_cv;
...
EXEC SQL EXECUTE
BEGIN
  IF :choice = 1 THEN
    OPEN :generic_cv FOR SELECT * FROM emp;
  ELSIF :choice = 2 THEN
    OPEN :generic_cv FOR SELECT * FROM dept;
  ELSIF :choice = 3 THEN
    OPEN :generic_cv FOR SELECT * FROM bonus;
  ELSIF :choice = 4 THEN
    OPEN :generic_cv FOR SELECT * FROM salgrade;
  END IF;
END;
END–EXEC;
```

You can also pass a cursor variable to PL/SQL by calling a stored procedure that declares a cursor variable as one of its formal parameters. For example, the following packaged procedure opens a cursor variable named `emp_cv`:

```sql
CREATE PACKAGE emp_data AS
...
  TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
  PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp);
END emp_data;

CREATE PACKAGE BODY emp_data AS
...
  PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp) IS
    BEGIN
      OPEN emp_cv FOR SELECT * FROM emp;
    END open_emp_cv;
END emp_data;
```
A Pro*C application might call the procedure, as follows:

```sql
EXEC SQL EXECUTE
BEGIN
    emp_data.open_emp_cv(:emp_cv);
END;
END-EXEC;
```

Alternatively, you can use a standalone procedure to open the cursor variable. Simply define the REF CURSOR type in a separate package, then reference that type in the standalone procedure. For instance, if you create the following (bodiless) package, you can create standalone procedures that reference the types it defines:

```sql
CREATE PACKAGE cv_types AS
    TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
    TYPE DeptCurTyp IS REF CURSOR RETURN dept%ROWTYPE;
    TYPE BonusCurTyp IS REF CURSOR RETURN bonus%ROWTYPE;
    ...
END cv_types;
```

In the following example, you create a standalone procedure that references the REF CURSOR type `EmpCurTyp`, which is defined in the package `cv_types`:

```sql
CREATE PROCEDURE open_emp_cv (emp_cv IN OUT cv_types.EmpCurTyp) AS
BEGIN
    OPEN emp_cv FOR SELECT * FROM emp;
END open_emp_cv;
```

To centralize data retrieval, you can group type-compatible queries in a stored procedure, as shown in the following example:

```sql
CREATE PACKAGE emp_data AS
    TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
    PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp, choice IN NUMBER);
END emp_data;
```

```sql
CREATE PACKAGE BODY emp_data AS
    PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp, choice IN NUMBER) IS
    BEGIN
        IF choice = 1 THEN
            OPEN emp_cv FOR SELECT * FROM emp WHERE comm IS NOT NULL;
        ELSIF choice = 2 THEN
            OPEN emp_cv FOR SELECT * FROM emp WHERE sal > 2500;
        ELSIF choice = 3 THEN
            OPEN emp_cv FOR SELECT * FROM emp WHERE deptno = 20;
        END IF;
    END open_emp_cv;
END emp_data;
```
Notice that the packaged procedure declares a selector as one of its formal parameters. When called, the procedure opens the cursor variable `emp_cv` for the chosen query. A Pro*C application might call the procedure, as follows:

```sql
EXEC SQL EXECUTE
  BEGIN
    emp_data.open_emp_cv(:emp_cv, :query_no);
  END;
END-EXEC;
```

After opening a cursor variable for a multi-row query, you use the `FETCH` statement to retrieve rows from the active set one at a time. Currently, you must execute the `FETCH` statement on the client side. In the following Pro*C example, you fetch rows into a host record (struct) named `emp_rec`:

```c
/* Exit loop when done fetching. */
EXEC SQL WHENEVER NOTFOUND DO break;
for (;;)
{
  /* Fetch row into record. */
  EXEC SQL FETCH :emp_cv INTO :emp_rec;
  /* Process the data record. */
}
```

Any variables in the associated query are evaluated only when the cursor variable is opened. To change the active set or the values of variables in the query, you must reopen the cursor variable with the variables set to their new values. However, you can use a different INTO clause on separate fetches with the same cursor variable. Each fetch retrieves another row from the same active set, as the following example shows:

```c
EXEC SQL WHENEVER NOTFOUND DO break;
for (;;)
{
  /* Fetch row from active set. */
  EXEC SQL FETCH :emp_cv INTO :emp_rec1;
  /* Fetch next row from same active set. */
  EXEC SQL FETCH :emp_cv INTO :emp_rec2;
  /* Process the data records. */
}
```

PL/SQL raises the predefined exception INVALID_CURSOR if you try to fetch from a closed or never-opened cursor variable. If you `FETCH` past the last row in the active set, the values of the target fields or variables are indeterminate. Eventually, the `FETCH` statement must fail to return a row; so when that happens, no exception is raised.
Closing a Cursor Variable  
You use the CLOSE statement to close a cursor variable, at which point its active set becomes undefined. The syntax follows:

```sql
CLOSE cursor_variable_name;
```

You can execute the CLOSE statement on the client side or server side. In the following Pro*C example, when the last row is processed, you close the cursor variable `emp_cv`:

```sql
EXEC SQL WHENEVER NOTFOUND DO break;
for (;;) {
  EXEC SQL FETCH :emp_cv INTO :emp_rec;
  /* Process the data record. */
}
/* Close cursor variable. */
EXEC SQL CLOSE :emp_cv;
```

PL/SQL raises the predefined exception INVALID_CURSOR if you try to close an already–closed or never–opened cursor variable.

Guidelines  
You can define subprograms that declare PL/SQL cursor variables as formal parameters and local variables. However, you cannot execute such subprograms unless each PL/SQL cursor variable points to a cursor work area designated by a host cursor variable. For example, the following procedure call raises an exception because the formal parameter `cv` is not bound to a host cursor variable:

```sql
DECLARE
  TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
  emp_cv EmpCurTyp;  -- declare local cursor variable
PROCEDURE open_emp_cv (cv IN OUT EmpCurTyp) IS
BEGIN
  OPEN cv FOR SELECT * FROM emp;
END;
BEGIN
  open_emp_cv(emp_cv);  -- causes 'invalid cursor' error
END;
```

You can make a PL/SQL cursor variable point to a valid cursor work area in the following ways:

- Assign a host cursor variable to a local PL/SQL cursor variable.
- Pass a host cursor variable to a subprogram that declares a cursor variable as its formal parameter.
- Assign or pass a PL/SQL cursor variable that already points to a cursor work area to another cursor variable.
Before trying to assign one PL/SQL cursor variable to another, make sure they have the same datatype. In the following example, although the cursor variables have the same return type, the assignment raises an exception because they have different datatypes:

```sql
DECLARE
  TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
  TYPE TmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
  ...
PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp,
                          tmp_cv IN OUT TmpCurTyp) IS
BEGIN
  ...
  emp_cv := tmp_cv;  -- causes 'wrong type' error
END;
```

Be careful when passing host cursor variables as parameters. PL/SQL raises the predefined exception `ROWTYPE_MISMATCH` if the return types of the actual and formal parameters are incompatible.

In the Pro*C example below, you define a packaged REF CURSOR type, specifying the return type `emp%ROWTYPE`. Next, you create a standalone procedure that references the new type. Then, inside a PL/SQL block, you open a host cursor variable for a query of the `dept` table. Later, when you pass the open host cursor variable to the standalone procedure, PL/SQL raises `ROWTYPE_MISMATCH` because the return types of the actual and formal parameters are incompatible.

```sql
CREATE PACKAGE cv_types AS
  TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
  ...
END cv_types;
...
CREATE PROCEDURE open_emp_cv (emp_cv IN OUT cv_types.EmpCurTyp) AS
BEGIN
  OPEN emp_cv FOR SELECT * FROM emp;
END open_emp_cv;
...
EXEC SQL EXECUTE
BEGIN
  OPEN :cv FOR SELECT * FROM dept;
  ...
  open_emp_cv(:cv);  -- raises ROWTYPE_MISMATCH
END;
END-EXEC;
```
Restrictions

Currently, cursor variables are subject to the following restrictions, which will be lifted by future releases of PL/SQL:

- You cannot declare cursor variables in a package. However, you can define REF CURSOR types in a package.
- Remote subprograms cannot return the values of cursor variables. Therefore, you cannot use a remote procedure to open a cursor variable.
- You cannot fetch from a cursor variable on the server side; you must fetch from it on the client side.
- The query associated with a cursor variable in an OPEN–FOR statement cannot be FOR UPDATE.
- You cannot use comparison operators to test cursor variables for equality, inequality, or nullity. For example, the following IF conditions are illegal:

  ```plsql
  PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp,
                         tmp_cv IN OUT TmpCurTyp) IS
  BEGIN
    ...
    IF emp_cv = tmp_cv THEN ... -- illegal
    IF emp_cv IS NULL THEN ... -- illegal
  END;
  ```

- You cannot assign nulls to a cursor variable. For example, the following assignment statement is illegal:

  ```plsql
  PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp) IS
  BEGIN
    emp_cv := NULL; -- illegal
    ...
  END;
  ```

- You cannot use REF CURSOR types to specify column types in a CREATE TABLE or CREATE VIEW statement. So, database columns cannot store the values of cursor variables.
- You cannot use a REF CURSOR type to specify the column type in a PL/SQL table, which means that rows in a PL/SQL table cannot store the values of cursor variables. For example, the following TABLE type definition is illegal:

  ```plsql
  DECLARE
    TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
    TYPE EmpCurTabTyp IS TABLE OF EmpCurTyp -- illegal
      INDEX BY BINARY_INTEGER;
  ```
• Cursors and cursor variables are not interoperable, meaning that you cannot use one where the other is expected. For example, the following cursor FOR loop is illegal:

```
DECLARE
    CURSOR emp_cur IS SELECT * FROM emp;  -- static cursor
    TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
    emp_cv EmpCurTyp;  -- cursor variable
BEGIN
    FOR emp_rec IN emp_cv LOOP ... -- illegal
    END LOOP;
END;
```

• You cannot use cursor variables with dynamic SQL.

### A Complete Example

The following Pro*C program prompts the user to select a database table, opens a cursor variable for a query of that table, then fetches rows returned by the query:

```c
#include <stdio.h>
#include <sqlca.h>
void sql_error();
main()
{
    char temp[32];
    EXEC SQL BEGIN DECLARE SECTION;
    char * uid = "scott/tiger";
    SQL_CURSOR generic_cv; /* cursor variable */
    int    table_num;        /* selector        */
    struct /* EMP record      */
    {
        int   emp_num;
        char  emp_name[11];
        char  job_title[10];
        int   manager;
        char  hire_date[10];
        float salary;
        float commission;
        int   dept_num;
    } emp_rec;
    struct /* DEPT record     */
    {
        int   dept_num;
        char  dept_name[15];
        char  location[14];
    } dept_rec;
```
struct                     /* BONUS record    */
{
    char  emp_name[11];
    char  job_title[10];
    float salary;
    float commission;
} bonus_rec;
EXEC SQL END DECLARE SECTION;

/* Handle Oracle Errors. */
EXEC SQL WHENEVER SQLERROR DO sql_error();
/* Connect to Oracle. */
EXEC SQL CONNECT :uid;

/* Initialize cursor variable. */
EXEC SQL ALLOCATE :generic_cv;

/* Exit loop when done fetching. */
EXEC SQL WHENEVER NOTFOUND DO break;
for (;;)
{
    printf("1 = EMP, 2 = DEPT, 3 = BONUS\n"):
    printf("\nEnter table number (0 to quit): ");
    gets(temp);
    table_num = atoi(temp);
    if (table_num <= 0) break;
    /* Open cursor variable. */
    EXEC SQL EXECUTE
    BEGIN
        IF :table_num = 1 THEN
            OPEN :generic_cv FOR SELECT * FROM emp;
        ELSIF :table_num = 2 THEN
            OPEN :generic_cv FOR SELECT * FROM dept;
        ELSIF :table_num = 3 THEN
            OPEN :generic_cv FOR SELECT * FROM bonus;
        END IF;
    END–EXEC;
    for (;;)
    {
        switch (table_num)
        {
        case 1:  /* Fetch row into EMP record. */
            EXEC SQL FETCH :generic_cv INTO :emp_rec;
            break;
        case 2:  /* Fetch row into DEPT record. */
            EXEC SQL FETCH :generic_cv INTO :dept_rec;
            break;
        }
Using Cursor Attributes

Each cursor or cursor variable has four attributes: %FOUND, %ISOPEN, %NOTFOUND, and %ROWCOUNT. When appended to the cursor or cursor variable, these attributes return useful information about the execution of a data manipulation statement. You can use cursor attributes in procedural statements but not in SQL statements.

Explicit Cursor Attributes

Explicit cursor attributes return information about the execution of a multi-row query. When an explicit cursor or a cursor variable is opened, the rows that satisfy the associated query are identified and form the active set. Rows are fetched from the active set one at a time.

%FOUND

After a cursor or cursor variable is opened but before the first fetch, %FOUND yields NULL. Thereafter, it yields TRUE if the last fetch returned a row, or FALSE if the last fetch failed to return a row. In the following example, you use %FOUND to select an action:

```
LOOP
    FETCH c1 INTO my_ename, my_sal, my_hiredate;
    IF c1%FOUND THEN  -- fetch succeeded
        ...
    ELSE  -- fetch failed, so exit loop
        EXIT;
    END IF;
```
If a cursor or cursor variable is not open, referencing it with %FOUND raises the predefined exception INVALID_CURSOR.

%ISOPEN
%ISOPEN yields TRUE if its cursor or cursor variable is open; otherwise, %ISOPEN yields FALSE. In the following example, you use %ISOPEN to select an action:

```plsql
IF c1%ISOPEN THEN  -- cursor is open
  ...
ELSE  -- cursor is closed, so open it
  OPEN c1;
END IF;
```

%NOTFOUND
%NOTFOUND is the logical opposite of %FOUND. %NOTFOUND yields FALSE if the last fetch returned a row, or TRUE if the last fetch failed to return a row. In the following example, you use %NOTFOUND to exit a loop when FETCH fails to return a row:

```plsql
LOOP
  FETCH c1 INTO my_ename, my_sal, my_hiredate;
  EXIT WHEN c1%NOTFOUND;
  ...
END LOOP;
```

If a cursor or cursor variable is not open, referencing it with %NOTFOUND raises INVALID_CURSOR.

%ROWCOUNT
When its cursor or cursor variable is opened, %ROWCOUNT is zeroed. Before the first fetch, %ROWCOUNT yields 0. Thereafter, it yields the number of rows fetched so far. The number is incremented if the last fetch returned a row. In the next example, you use %ROWCOUNT to take action if more than ten rows have been fetched:

```plsql
LOOP
  FETCH c1 INTO my_ename, my_deptno;
  IF c1%ROWCOUNT > 10 THEN
    ...
  END IF;
  ...
END LOOP;
```

If a cursor or cursor variable is not open, referencing it with %ROWCOUNT raises INVALID_CURSOR.
Table 4–1 shows what each cursor attribute yields before and after you execute an OPEN, FETCH, or CLOSE statement.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>%FOUND</th>
<th>%ISOPEN</th>
<th>%NOTFOUND</th>
<th>%ROWCOUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPEN before</td>
<td>exception</td>
<td>FALSE</td>
<td>exception</td>
<td>exception</td>
</tr>
<tr>
<td>after</td>
<td>NULL</td>
<td>TRUE</td>
<td>NULL</td>
<td>0</td>
</tr>
<tr>
<td>first FETCH</td>
<td>before</td>
<td>NULL</td>
<td>TRUE</td>
<td>NULL</td>
</tr>
<tr>
<td>after</td>
<td>TRUE</td>
<td>TRUE</td>
<td>FALSE</td>
<td>1</td>
</tr>
<tr>
<td>middle FETCH</td>
<td>before</td>
<td>TRUE</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>after</td>
<td>TRUE</td>
<td>TRUE</td>
<td>FALSE</td>
<td>data dependent</td>
</tr>
<tr>
<td>last FETCH</td>
<td>before</td>
<td>TRUE</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>after</td>
<td>FALSE</td>
<td>TRUE</td>
<td>TRUE</td>
<td>data dependent</td>
</tr>
<tr>
<td>CLOSE before</td>
<td>FALSE</td>
<td>TRUE</td>
<td>TRUE</td>
<td>data dependent</td>
</tr>
<tr>
<td>after</td>
<td>exception</td>
<td>FALSE</td>
<td>exception</td>
<td>exception</td>
</tr>
</tbody>
</table>

Notes: Referencing %FOUND, %NOTFOUND, or %ROWCOUNT before a cursor is opened or after it is closed raises INVALID_CURSOR.

After the first FETCH, if the active set was empty, %FOUND yields FALSE, %NOTFOUND yields TRUE, and %ROWCOUNT yields 0.

Table 4–1 Cursor Values

Some Examples

Suppose you have a table named data_table that holds data collected from laboratory experiments, and you want to analyze the data from experiment 1. In the following example, you compute the results and store them in a database table named temp:

```sql
DECLARE
    num1 data_table.n1%TYPE;  -- Declare variables having same types as database columns
    num2 data_table.n2%TYPE;
    num3 data_table.n3%TYPE;
    result temp.col1%TYPE;
CURSOR c1 IS
    SELECT n1, n2, n3 FROM data_table WHERE exper_num = 1;
BEGIN
    OPEN c1;
    LOOP
        FETCH c1 INTO num1, num2, num3;
        EXIT WHEN c1%NOTFOUND;
        -- The c1%NOTFOUND condition yields TRUE when FETCH finds no more rows
        result := num2/(num1 + num3);
        INSERT INTO temp VALUES (result, NULL, NULL);
    END LOOP;
    CLOSE c1;
    COMMIT;
END;
```

Some Examples
In the next example, you check all storage bins that contain part number 5469, withdrawing their contents until you accumulate 1000 units:

```
DECLARE
  CURSOR bin_cur(part_number NUMBER) IS
    SELECT amt_in_bin FROM bins
    WHERE part_num = part_number AND amt_in_bin > 0
    ORDER BY bin_num
    FOR UPDATE OF amt_in_bin;
  bin_amt        bins.amt_in_bin%TYPE;
  total_so_far   NUMBER(5) := 0;
  amount_needed  CONSTANT NUMBER(5) := 1000;
  bins_looked_at NUMBER(3) := 0;
BEGIN
  OPEN bin_cur(5469);
  WHILE total_so_far < amount_needed LOOP
    FETCH bin_cur INTO bin_amt;
    EXIT WHEN bin_cur%NOTFOUND;
    -- if we exit, there's not enough to fill the order
    bins_looked_at := bins_looked_at + 1;
    IF total_so_far + bin_amt < amount_needed THEN
      UPDATE bins SET amt_in_bin = 0
      WHERE CURRENT OF bin_cur;
      -- take everything in the bin
      total_so_far := total_so_far + bin_amt;
    ELSE  -- we finally have enough
      UPDATE bins SET amt_in_bin = amt_in_bin
      - (amount_needed - total_so_far)
      WHERE CURRENT OF bin_cur;
      total_so_far := amount_needed;
    END IF;
  END LOOP;
  CLOSE bin_cur;

  INSERT INTO temp VALUES (NULL, bins_looked_at, '<< bins looked at');
  COMMIT;
END;
```
Implicit Cursor Attributes

Implicit cursor attributes return information about the execution of an INSERT, UPDATE, DELETE, or SELECT INTO statement. The values of the cursor attributes always refer to the most recently executed SQL statement. Before Oracle opens the SQL cursor, the implicit cursor attributes yield NULL.

%FOUND

Until a SQL data manipulation statement is executed, %FOUND yields NULL. Thereafter, %FOUND yields TRUE if an INSERT, UPDATE, or DELETE statement affected one or more rows, or a SELECT INTO statement returned one or more rows. Otherwise, %FOUND yields FALSE. In the following example, you use %FOUND to insert a row if a delete succeeds:

```sql
DELETE FROM emp WHERE empno = my_empno;
IF SQL%FOUND THEN  -- delete succeeded
    INSERT INTO new_emp VALUES (my_empno, my_ename, ...);
...
END IF;
```

%ISOPEN

Oracle closes the SQL cursor automatically after executing its associated SQL statement. As a result, %ISOPEN always yields FALSE.

%NOTFOUND

%NOTFOUND is the logical opposite of %FOUND. %NOTFOUND yields TRUE if an INSERT, UPDATE, or DELETE statement affected no rows, or a SELECT INTO statement returned no rows. Otherwise, %NOTFOUND yields FALSE. In this example, you use %NOTFOUND to insert a new row if an update fails:

```sql
UPDATE emp SET sal = sal * 1.05 WHERE empno = my_empno;
IF SQL%NOTFOUND THEN  -- update failed
    INSERT INTO errors VALUES (...);
END IF;
```

%ROWCOUNT

%ROWCOUNT yields the number of rows affected by an INSERT, UPDATE, or DELETE statement, or returned by a SELECT INTO statement. %ROWCOUNT yields 0 if an INSERT, UPDATE, or DELETE statement affected no rows, or a SELECT INTO statement returned no rows. In the following example, you use %ROWCOUNT to take action if more than ten rows have been deleted:

```sql
DELETE FROM emp WHERE ...
IF SQL%ROWCOUNT > 10 THEN  -- more than 10 rows were deleted
...
END IF;
```

If a SELECT INTO statement returns more than one row, PL/SQL raises the predefined exception TOO_MANY_ROWS and %ROWCOUNT yields 1, not the actual number of rows that satisfy the query.
Guidelines

The values of the cursor attributes always refer to the most recently executed SQL statement, wherever that statement is. It might be in a different scope (for example, in a sub-block). So, if you want to save an attribute value for later use, assign it to a Boolean variable immediately. In the following example, relying on the IF condition is dangerous because the procedure `check_status` might have changed the value of `%NOTFOUND`:

```sql
UPDATE parts SET quantity = quantity - 1 WHERE partno = part_id;
check_status(part_id);  -- procedure call
IF SQL%NOTFOUND THEN -- dangerous!
```

You can debug the code as follows:

```sql
UPDATE parts SET quantity = quantity - 1 WHERE partno = part_id;
sql_notfound := SQL%NOTFOUND;  -- assign value to Boolean variable
check_status(part_id);
IF sql_notfound THEN ...
```

If a SELECT INTO statement fails to return a row, PL/SQL raises the predefined exception `NO_DATA_FOUND` whether you check `%NOTFOUND` on the next line or not. Consider the following example:

```sql
BEGIN
...
SELECT sal INTO my_sal FROM emp WHERE empno = my_empno;
   -- might raise NO_DATA_FOUND
IF SQL%NOTFOUND THEN -- condition tested only when false
   ...
   -- this action is never taken
END IF;
```

The check is useless because the IF condition is tested only when `%NOTFOUND` is false. When PL/SQL raises `NO_DATA_FOUND`, normal execution stops and control transfers to the exception-handling part of the block.

However, a SELECT INTO statement that calls a SQL group function never raises `NO_DATA_FOUND` because group functions always return a value or a null. In such cases, `%NOTFOUND` yields FALSE, as the following example shows:

```sql
BEGIN
...
SELECT MAX(sal) INTO my_sal FROM emp WHERE deptno = my_deptno;
   -- never raises NO_DATA_FOUND
IF SQL%NOTFOUND THEN -- always tested but never true
   ...
   -- this action is never taken
END IF;
EXCEPTION
   WHEN NO_DATA_FOUND THEN -- never invoked
   ...
```
Processing Transactions

This section explains how to do transaction processing. You learn the basic techniques that safeguard the consistency of your database, including how to control whether changes to Oracle data are made permanent or undone. Before delving into the subject, you should know the terms defined below.

The jobs or tasks that Oracle manages are called sessions. A user session is started when you run an application program or an Oracle tool and connect to Oracle. To allow user sessions to work “simultaneously” and share computer resources, Oracle must control concurrency, the accessing of the same data by many users. Without adequate concurrency controls, there might be a loss of data integrity. That is, changes to data or structures might be made in the wrong order.

Oracle uses locks to control concurrent access to data. A lock gives you temporary ownership of a database resource such as a table or row of data. Thus, data cannot be changed by other users until you finish with it. You need never explicitly lock a resource because default locking mechanisms protect Oracle data and structures. However, you can request data locks on tables or rows when it is to your advantage to override default locking. You can choose from several modes of locking such as row share and exclusive.

A deadlock can occur when two or more users try to access the same database object. For example, two users updating the same table might wait if each tries to update a row currently locked by the other. Because each user is waiting for resources held by another user, neither can continue until Oracle breaks the deadlock by signaling an error to the last participating transaction.

When a table is being queried by one user and updated by another at the same time, Oracle generates a read–consistent view of the data for the query. That is, once a query begins and as it proceeds, the data read by the query does not change. As update activity continues, Oracle takes snapshots of the table’s data and records changes in a rollback segment. Oracle uses information in the rollback segment to build read–consistent query results and to undo changes if necessary.
Oracle is transaction oriented; that is, it uses transactions to ensure data integrity. A transaction is a series of one or more logically related SQL statements that accomplish a task. Oracle treats the series of SQL statements as a unit so that all the changes brought about by the statements are either committed (made permanent) or rolled back (undone) at the same time. If your program fails in the middle of a transaction, the database is automatically restored to its former state.

The first SQL statement in your program begins a transaction. When one transaction ends, the next SQL statement automatically begins another transaction. Thus, every SQL statement is part of a transaction. A distributed transaction includes at least one SQL statement that updates data at multiple nodes in a distributed database.

The COMMIT and ROLLBACK statements ensure that all database changes brought about by SQL operations are either made permanent or undone at the same time. All the SQL statements executed since the last commit or rollback make up the current transaction. The SAVEPOINT statement names and marks the current point in the processing of a transaction.

The COMMIT statement ends the current transaction and makes permanent any changes made during that transaction. Until you commit the changes, other users cannot access the changed data; they see the data as it was before you made the changes.

Consider a simple transaction that transfers money from one bank account to another. The transaction requires two updates because it debits the first account, then credits the second. In the example below, after crediting the second account, you issue a commit, which makes the changes permanent. Only then do other users see the changes.

```sql
BEGIN
  ...
  UPDATE accts SET bal = my_bal - debit
    WHERE acctno = 7715;
  ...
  UPDATE accts SET bal = my_bal + credit
    WHERE acctno = 7720;
  COMMIT WORK;
END;
```

The COMMIT statement releases all row and table locks. It also erases any savepoints (discussed later) marked since the last commit or rollback. The optional keyword WORK has no effect other than to improve readability. The keyword END signals the end of a PL/SQL block, not the end of a transaction. Just as a block can span multiple transactions, a transaction can span multiple blocks.
The COMMENT clause lets you specify a comment to be associated with a distributed transaction. When you issue a commit, changes to each database affected by a distributed transaction are made permanent. However, if a network or machine fails during the commit, the state of the distributed transaction might be unknown or in doubt. In that case, Oracle stores the text specified by COMMENT in the data dictionary along with the transaction ID. The text must be a quoted literal up to 50 characters long. An example follows:

```
COMMIT COMMENT 'In-doubt order transaction; notify Order Entry';
```

The ROLLBACK statement ends the current transaction and undoes any changes made during that transaction. Rolling back is useful for two reasons. First, if you make a mistake like deleting the wrong row from a table, a rollback restores the original data. Second, if you start a transaction that you cannot finish because an exception is raised or a SQL statement fails, a rollback lets you return to the starting point to take corrective action and perhaps try again.

Consider the example below, in which you insert information about an employee into three different database tables. All three tables have a column that holds employee numbers and is constrained by a unique index. If an INSERT statement tries to store a duplicate employee number, the predefined exception DUP_VAL_ON_INDEX is raised. In that case, you want to undo all changes. So, you issue a rollback in the exception handler.

```
DECLARE
  emp_id  INTEGER;
  ...
BEGIN
  SELECT empno, ... INTO emp_id, ... FROM new_emp WHERE ...
  ...
  INSERT INTO emp VALUES (emp_id, ...);
  INSERT INTO tax VALUES (emp_id, ...);
  INSERT INTO pay VALUES (emp_id, ...);
  ...
EXCEPTION
  WHEN DUP_VAL_ON_INDEX THEN
    ROLLBACK;
  ...
END;
```

In the following example, you specify a comment to be associated with a distributed transaction:

```
ROLLBACK COMMENT 'In-doubt sales transaction; notify Sales Dept';
```
Before executing a SQL statement, Oracle marks an implicit savepoint. Then, if the statement fails, Oracle rolls it back automatically. For example, if an INSERT statement raises an exception by trying to insert a duplicate value in a unique index, the statement is rolled back. Only work started by the failed SQL statement is lost. Work done before that statement in the current transaction is kept.

Oracle can also roll back single SQL statements to break deadlocks. Oracle signals an error to one of the participating transactions and rolls back the current statement in that transaction.

Before executing a SQL statement, Oracle must parse it, that is, examine it to make sure it follows syntax rules and refers to valid database objects. Errors detected while executing a SQL statement cause a rollback, but errors detected while parsing the statement do not.

SAVEPOINT names and marks the current point in the processing of a transaction. Used with the ROLLBACK TO statement, savepoints let you undo parts of a transaction instead of the whole transaction. In the example below, you mark a savepoint before doing an insert. If the INSERT statement tries to store a duplicate value in the empno column, the predefined exception DUP_VAL_ON_INDEX is raised. In that case, you roll back to the savepoint, undoing just the insert.

```plsql
DECLARE
  emp_id  emp.empno%TYPE;
BEGIN
  ...
  UPDATE emp SET ... WHERE empno = emp_id;
  DELETE FROM emp WHERE ...
  ...
  SAVEPOINT do_insert;
  INSERT INTO emp VALUES (emp_id, ...);
EXCEPTION
  WHEN DUP_VAL_ON_INDEX THEN
    ROLLBACK TO do_insert;
END;
```

When you roll back to a savepoint, any savepoints marked after that savepoint are erased. However, the savepoint to which you roll back is not erased. For example, if you mark five savepoints, then roll back to the third, only the fourth and fifth are erased. A simple rollback or commit erases all savepoints.

If you mark a savepoint within a recursive subprogram, new instances of the SAVEPOINT statement are executed at each level in the recursive descent. However, you can only rollback to the most recently marked savepoint.
Savepoint names are undeclared identifiers and can be reused within a transaction. This moves the savepoint from its old position to the current point in the transaction. Thus, a rollback to the savepoint affects only the current part of your transaction. An example follows:

```
BEGIN
  ...
  SAVEPOINT my_point;
  UPDATE emp SET ... WHERE empno = emp_id;
  ...
  SAVEPOINT my_point;  -- move my_point to current point
  INSERT INTO emp VALUES (emp_id, ...);
  ...
EXCEPTION
  WHEN OTHERS THEN
    ROLLBACK TO my_point;
END;
```

By default, the number of active savepoints per session is limited to five. An active savepoint is one marked since the last commit or rollback. You or your DBA can raise the limit (up to 255) by increasing the value of the Oracle initialization parameter SAVEPOINTS.

**Implicit Rollbacks**

Before executing an INSERT, UPDATE, or DELETE statement, Oracle marks an implicit savepoint (unavailable to you). If the statement fails, Oracle rolls back to the savepoint. Normally, just the failed SQL statement is rolled back, not the whole transaction. However, if the statement raises an unhandled exception, the host environment determines what is rolled back.

If you exit a stored subprogram with an unhandled exception, PL/SQL does not assign values to OUT parameters. Also, PL/SQL does not roll back database work done by the subprogram.

**Ending Transactions**

It is good programming practice to commit or roll back every transaction explicitly. Whether you issue the commit or rollback in your PL/SQL program or in the host environment depends on the flow of application logic. If you neglect to commit or roll back a transaction explicitly, the host environment determines its final state.

For example, in the SQL*Plus environment, if your PL/SQL block does not include a COMMIT or ROLLBACK statement, the final state of your transaction depends on what you do after running the block. If you execute a data definition, data control, or COMMIT statement or if you issue the EXIT, DISCONNECT, or QUIT command, Oracle commits the transaction. If you execute a ROLLBACK statement or abort the SQL*Plus session, Oracle rolls back the transaction.
In the Oracle Precompiler environment, if your program does not terminate normally, Oracle rolls back your transaction. A program terminates normally when it explicitly commits or rolls back work and disconnects from Oracle using the RELEASE parameter, as follows:

EXEC SQL COMMIT WORK RELEASE;

In the OCI environment, if you issue the OLOGOF call, Oracle automatically commits your transaction. Otherwise, Oracle rolls back the transaction.

**Using SET TRANSACTION**

You use the SET TRANSACTION statement to begin a read–only or read–write transaction, or to assign your current transaction to a specified rollback segment. Read–only transactions are useful for running multiple queries against one or more tables while other users update the same tables.

During a read–only transaction, all queries refer to the same snapshot of the database, providing a multi–table, multi–query, read–consistent view. Other users can continue to query or update data as usual. A commit or rollback ends the transaction. In the example below, as a store manager, you use a read–only transaction to gather sales figures for the day, the past week, and the past month. The figures are unaffected by other users updating the database during the transaction.

```sql
DECLARE
  daily_sales   REAL;
  weekly_sales  REAL;
  monthly_sales REAL;
BEGIN
  ...;
  COMMIT;  -- ends previous transaction
  SET TRANSACTION READ ONLY;
  SELECT SUM(amt) INTO daily_sales FROM sales
    WHERE dte = SYSDATE;
  SELECT SUM(amt) INTO weekly_sales FROM sales
    WHERE dte > SYSDATE - 7;
  SELECT SUM(amt) INTO monthly_sales FROM sales
    WHERE dte > SYSDATE - 30;
  COMMIT;  -- ends read-only transaction
  ...;
END;
```

The SET TRANSACTION statement must be the first SQL statement in a read–only transaction and can only appear once in a transaction. If you set a transaction to READ ONLY, subsequent queries see only changes committed before the transaction began. The use of READ ONLY does not affect other users or transactions.
Restrictions

Only the SELECT INTO, OPEN, FETCH, CLOSE, LOCK TABLE, COMMIT, and ROLLBACK statements are allowed in a read-only transaction. Also, queries cannot be FOR UPDATE.

Overriding Default Locking

By default, Oracle locks data structures for you automatically. However, you can request specific data locks on rows or tables when it is to your advantage to override default locking. Explicit locking lets you share or deny access to a table for the duration of a transaction.

With the SELECT FOR UPDATE statement, you can explicitly lock specific rows of a table to make sure they do not change before an update or delete is executed. However, Oracle automatically obtains row-level locks at update or delete time. So, use the FOR UPDATE clause only if you want to lock the rows before the update or delete.

You can explicitly lock entire tables using the LOCK TABLE statement.

Using FOR UPDATE

When you declare a cursor that will be referenced in the CURRENT OF clause of an UPDATE or DELETE statement, you must use the FOR UPDATE clause to acquire exclusive row locks. The FOR UPDATE clause must appear at the end of the cursor declaration, as the following example shows:

```sql
DECLARE
  CURSOR c1 IS SELECT empno, sal FROM emp
  WHERE job = 'SALESMAN' AND comm > sal FOR UPDATE;
```

The FOR UPDATE clause identifies the rows that will be updated or deleted, then locks each row in the active set. This is useful when you want to base an update on the existing values in a row. In that case, you must make sure the row is not changed by another user before the update.

All rows are locked when you open the cursor, not as they are fetched. The rows are unlocked when you commit or roll back the transaction. So, you cannot fetch from a FOR UPDATE cursor after a commit. (For a workaround, see “Fetching Across Commits” on page 4–43.)

When querying multiple tables, you can use the FOR UPDATE clause to confine row locking to particular tables. Rows in a table are locked only if the FOR UPDATE OF clause refers to a column in that table. For example, the following query locks rows in the `emp` table but not in the `dept` table:

```sql
DECLARE
  CURSOR c1 IS SELECT ename, dname FROM emp, dept
  WHERE emp.deptno = dept.deptno AND job = 'MANAGER'
  FOR UPDATE OF sal;
```
You use the CURRENT OF clause in an UPDATE or DELETE statement to refer to the latest row fetched from a cursor, as the following example shows:

DECLARE
  CURSOR c1 IS SELECT empno, job, sal FROM emp FOR UPDATE;
  ...
BEGIN
  OPEN c1;
  LOOP
    FETCH c1 INTO ...
    ...
    UPDATE emp SET sal = new_sal WHERE CURRENT OF c1;
  END LOOP;
  ...
END;

Using LOCK TABLE

You use the LOCK TABLE statement to lock entire database tables in a specified lock mode so that you can share or deny access to them. For example, the statement below locks the emp table in row share mode. Row share locks allow concurrent access to a table; they prevent other users from locking the entire table for exclusive use. Table locks are released when your transaction issues a commit or rollback.

LOCK TABLE emp IN ROW SHARE MODE NOWAIT;

The lock mode determines what other locks can be placed on the table. For example, many users can acquire row share locks on a table at the same time, but only one user at a time can acquire an exclusive lock. While one user has an exclusive lock on a table, no other users can insert, delete, or update rows in that table. For more information about lock modes, see Oracle7 Server Application Developer's Guide.

The optional keyword NOWAIT tells Oracle not to wait if the table has been locked by another user. Control is immediately returned to your program so that it can do other work before trying again to acquire the lock. If you omit the keyword NOWAIT, Oracle waits until the table is available; the wait has no set limit.

A table lock never keeps other users from querying a table, and a query never acquires a table lock. Only if two different transactions try to modify the same row will one transaction wait for the other to complete.

Obtaining Locks

If your program includes SQL locking statements, make sure the Oracle users requesting locks have the privileges needed to obtain the locks. Your DBA can lock any table. Other users can lock tables they own or tables for which they have a privilege, such as SELECT, INSERT, UPDATE, or DELETE.
Fetching Across Commits

Remember, the FOR UPDATE clause acquires exclusive row locks. All rows are locked when you open the cursor, and they are unlocked when you commit your transaction. So, you cannot fetch from a FOR UPDATE cursor after a commit. If you do, PL/SQL raises an exception. In the following example, the cursor FOR loop fails after the tenth insert:

```sql
DECLARE
  CURSOR c1 IS SELECT ename FROM emp FOR UPDATE OF sal;
  ctr NUMBER := 0;
BEGIN
  FOR emp_rec IN c1 LOOP  -- FETCHes implicitly
    ... 
    ctr := ctr + 1;
    INSERT INTO temp VALUES (ctr, 'still going');
    IF ctr >= 10 THEN
      COMMIT;  -- releases locks
    END IF;
  END LOOP;
END;
```

If you want to fetch across commits, do not use the FOR UPDATE and CURRENT OF clauses. Instead, use the ROWID pseudocolumn to mimic the CURRENT OF clause. Simply select the rowid of each row into a ROWID variable. Then, use the rowid to identify the current row during subsequent updates and deletes. An example follows:

```sql
DECLARE
  CURSOR c1 IS SELECT ename, job, rowid FROM emp;
  my_ename emp.ename%TYPE;
  my_job    emp.job%TYPE;
  my_rowid  ROWID;
BEGIN
  OPEN c1;
  LOOP
    FETCH c1 INTO my_ename, my_job, my_rowid;
    EXIT WHEN c1%NOTFOUND;
    UPDATE emp SET sal = sal * 1.05 WHERE rowid = my_rowid;
    -- this mimics WHERE CURRENT OF c1
    COMMIT;
  END LOOP;
END;
```

Be careful. In the last example, the fetched rows are not locked because no FOR UPDATE clause is used. So, other users might unintentionally overwrite your changes. Also, the cursor must have a read-consistent view of the data, so rollback segments used in the update are not released until the cursor is closed. This can slow down processing when many rows are updated.
Dealing with Size Limitations

PL/SQL was designed primarily for transaction processing. As a result, the PL/SQL compiler limits the number of tokens a block can generate. Blocks that exceed the limit cause a program too large compilation error. Generally, blocks larger than 64K exceed the token limit. However, much smaller blocks can exceed the limit if they contain many variables or complex SQL statements.

The best solution to this problem is to modularize your program by defining subprograms (which can be stored in an Oracle database). For more information, see Chapter 6.

Another solution is to break the block into two sub–blocks. Before the first block terminates, have it insert any data the second block needs into a database table called temp (for example). When the second block starts executing, have it select the data from temp. This approximates the passing of parameters from one procedure to another. The following example shows two “parameter passing” PL/SQL blocks in a SQL*Plus script:

```sql
DECLARE
    mode   NUMBER;
    median NUMBER;
BEGIN
    ...    
    INSERT INTO temp (col1, col2, col3)
        VALUES (mode, median, 'blockA');
END;
/
    ...
```
DECLARE
    mode NUMBER;
    median NUMBER;
BEGIN
    SELECT col1, col2 INTO mode, median FROM temp
    WHERE col3 = 'blockA';
    ...
END;
/

The previous method works unless you must re-execute the first block while the second block is still executing or unless two or more users must run the script concurrently. To avoid these restrictions, embed your PL/SQL blocks in a third-generation host language such as C, COBOL, or FORTRAN. That way, you can re-execute the first block using flow-of-control statements. Also, you can store data in global host variables instead of using a temporary database table. In the following example, you embed two PL/SQL blocks in a Pro*C program:

EXEC SQL BEGIN DECLARE SECTION;
    int   my_empno;
    float my_sal, my_comm;
    short comm_ind;
    ...
EXEC SQL END DECLARE SECTION;
...
EXEC SQL EXECUTE
BEGIN
    ...
    SELECT sal, comm INTO :my_sal, :my_comm, comm_ind FROM emp
    WHERE empno = :my_empno;
    IF :my_comm > 1000 THEN
        UPDATE emp SET sal = :my_sal WHERE empno = :my_empno;
    END IF;
END;
END-EXEC;
...
EXEC SQL EXECUTE
BEGIN
    ...
    IF :my_comm > 1000 THEN
        :my_sal := :my_sal * 1.10;
        UPDATE emp SET sal = :my_sal WHERE empno = :my_empno;
    END IF;
END;
END-EXEC;
...
CHAPTER 5

Error Handling

There is nothing more exhilarating than to be shot at without result.

Winston Churchill

Runtime errors arise from design faults, coding mistakes, hardware failures, and many other sources. Although you cannot anticipate all possible errors, you can plan to handle certain kinds of errors meaningful to your PL/SQL program.

With many programming languages, unless you disable error checking, a runtime error such as stack overflow or division by zero stops normal processing and returns control to the operating system. With PL/SQL, a mechanism called exception handling lets you “bulletproof” your program so that it can continue operating in the presence of errors.
Overview

In PL/SQL, a warning or error condition is called an exception. Exceptions can be internally defined (by the runtime system) or user defined. Examples of internally defined exceptions include division by zero and out of memory. Some common internal exceptions have predefined names, such as ZERO_DIVIDE and STORAGE_ERROR. The other internal exceptions can be given names.

You can define exceptions of your own in the declarative part of any PL/SQL block, subprogram, or package. For example, you might define an exception named insufficient_funds to flag overdrawn bank accounts. Unlike internal exceptions, user–defined exceptions must be given names.

When an error occurs, an exception is raised. That is, normal execution stops and control transfers to the exception–handling part of your PL/SQL block or subprogram. Internal exceptions are raised implicitly (automatically) by the runtime system. User–defined exceptions must be raised explicitly by RAISE statements, which can also raise predefined exceptions.

To handle raised exceptions, you write separate routines called exception handlers. After an exception handler runs, the current block stops executing and the enclosing block resumes with the next statement. If there is no enclosing block, control returns to the host environment.

In the example below, you calculate and store a price–to–earnings ratio for a company with ticker symbol XYZ. If the company has zero earnings, the predefined exception ZERO_DIVIDE is raised. This stops normal execution of the block and transfers control to the exception handlers. The optional OTHERS handler catches all exceptions that the block does not name specifically.

```
DECLARE
    pe_ratio NUMBER(3,1);
BEGIN
    SELECT price / earnings INTO pe_ratio FROM stocks
        WHERE symbol = 'XYZ';  -- might cause division-by-zero error
    INSERT INTO stats (symbol, ratio) VALUES ('XYZ', pe_ratio);
    COMMIT;
EXCEPTION
    WHEN ZERO_DIVIDE THEN  -- handles 'division by zero' error
        INSERT INTO stats (symbol, ratio) VALUES ('XYZ', NULL);
    COMMIT;
    ...
    WHEN OTHERS THEN  -- handles all other errors
        ROLLBACK;
END;   -- exception handlers and block end here
```
The last example illustrates exception handling, not the effective use of INSERT statements. For example, a better way to do the insert follows:

```
INSERT INTO stats (symbol, ratio)
    SELECT symbol, DECODE(earnings, 0, NULL, price / earnings)
    FROM stocks WHERE symbol = 'XYZ';
```

In this example, a subquery supplies values to the INSERT statement. If earnings are zero, the function DECODE returns a null. Otherwise, DECODE returns the price-to-earnings ratio.

---

**Advantages and Disadvantages of Exceptions**

Using exceptions for error handling has several advantages. Without exception handling, every time you issue a command, you must check for execution errors, as follows:

```
BEGIN
  SELECT ... 
    -- check for 'no data found' error
  SELECT ... 
    -- check for 'no data found' error
  SELECT ... 
    -- check for 'no data found' error
  ... 
END;
```

Error processing is not clearly separated from normal processing; nor is it robust. If you neglect to code a check, the error goes undetected and is likely to cause other, seemingly unrelated errors.

With exceptions, you can handle errors conveniently without the need to code multiple checks, as follows:

```
BEGIN
  SELECT ... 
  SELECT ... 
  SELECT ... 
...
EXCEPTION
  WHEN NO_DATA_FOUND THEN  -- catches all 'no data found' errors
    ... 
END;
```

Notice how exceptions improve readability by letting you isolate error-handling routines. The primary algorithm is not obscured by error recovery algorithms.
Exceptions also improve reliability. You need not worry about checking for an error at every point it might occur. Just add an exception handler to your PL/SQL block. If the exception is ever raised in that block (or any sub-block), you can be sure it will be handled.

Disadvantages

Using exceptions for error handling has two disadvantages. First, exceptions can trap only runtime errors. Therefore, a PL/SQL program cannot trap and recover from compile-time (syntax and semantic) errors such as `table or view does not exist`.

Second, exceptions can mask the statement that caused an error, as the following example shows:

```plsql
BEGIN
  SELECT ...  
  SELECT ...  
  SELECT ...  
  ...  
EXCEPTION
  WHEN NO_DATA_FOUND THEN ...
      -- Which SELECT statement caused the error?
END;
```

Normally, this is not a problem. But, if the need arises, you can use a locator variable to track statement execution, as follows:

```plsql
DECLARE
  stmt INTEGER := 1;  -- designates 1st SELECT statement
BEGIN
  SELECT ...  
  stmt := 2;  -- designates 2nd SELECT statement
  SELECT ...  
  stmt := 3;  -- designates 3rd SELECT statement
  SELECT ...  
  ...  
EXCEPTION
  WHEN NO_DATA_FOUND THEN
      INSERT INTO errors VALUES ('Error in statement ' || stmt);  
      ...  
END;
```
Predefined Exceptions

An internal exception is raised implicitly whenever your PL/SQL program violates an Oracle rule or exceeds a system-dependent limit. Every Oracle error has a number, but exceptions must be handled by name. So, PL/SQL predefines some common Oracle errors as exceptions. For example, PL/SQL raises the predefined exception NO_DATA_FOUND if a SELECT INTO statement returns no rows.

To handle other Oracle errors, you can use the OTHERS handler. The error-reporting functions SQLCODE and SQLERRM are especially useful in the OTHERS handler because they return the Oracle error code and message text. Alternatively, you can use the pragma EXCEPTION_INIT to associate exception names with Oracle error numbers. (See “Using EXCEPTION_INIT” on page 5–9.)

PL/SQL declares predefined exceptions globally in package STANDARD, which defines the PL/SQL environment. So, you need not declare them yourself. You can write handlers for predefined exceptions using the names shown in the list below. Also shown are the corresponding Oracle error codes and SQLCODE return values.

<table>
<thead>
<tr>
<th>Exception Name</th>
<th>Oracle Error</th>
<th>SQLCODE Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURSOR_ALREADY_OPEN</td>
<td>ORA-06511</td>
<td>-6511</td>
</tr>
<tr>
<td>DUP_VAL_ON_INDEX</td>
<td>ORA-00001</td>
<td>-1</td>
</tr>
<tr>
<td>INVALID_CURSOR</td>
<td>ORA-01001</td>
<td>-1001</td>
</tr>
<tr>
<td>INVALID_NUMBER</td>
<td>ORA-01722</td>
<td>-1722</td>
</tr>
<tr>
<td>LOGIN_DENIED</td>
<td>ORA-01017</td>
<td>-1017</td>
</tr>
<tr>
<td>NO_DATA_FOUND</td>
<td>ORA-01403</td>
<td>+100</td>
</tr>
<tr>
<td>NOT_LOGGED_ON</td>
<td>ORA-01012</td>
<td>-1012</td>
</tr>
<tr>

<td>-1422</td>
</tr>
<tr>
<td>VALUE_ERROR</td>
<td>ORA-06502</td>
<td>-6502</td>
</tr>
<tr>
<td>ZERO_DIVIDE</td>
<td>ORA-01476</td>
<td>-1476</td>
</tr>
</tbody>
</table>

For a complete list of the messages that Oracle or PL/SQL might issue, see Oracle7 Server Messages.
Brief descriptions of the predefined exceptions follow:

**CURSOR_ALREADY_OPEN** is raised if you try to open an already open cursor. You must close a cursor before you can reopen it.

A cursor FOR loop automatically opens the cursor to which it refers. Therefore, you cannot enter the loop if that cursor is already open, nor can you open that cursor inside the loop.

**DUP_VAL_ON_INDEX** is raised if you try to store duplicate values in a database column that is constrained by a unique index.

**INVALID_CURSOR** is raised if you try an illegal cursor operation. For example, INVALID_CURSOR is raised if you close an unopened cursor.

**INVALID_NUMBER** is raised in a SQL statement if the conversion of a character string to a number fails because the string does not represent a valid number. For example, the following INSERT statement raises **INVALID_NUMBER** when Oracle tries to convert ‘HALL’ to a number:

```sql
INSERT INTO emp (empno, ename, deptno) VALUES ('HALL', 7888, 20);
```

In procedural statements, **VALUE_ERROR** is raised instead.

**LOGIN_DENIED** is raised if you try logging on to Oracle with an invalid username/password.

**NO_DATA_FOUND** is raised if a SELECT INTO statement returns no rows or if you reference an uninitialized row in a PL/SQL table. The FETCH statement is expected to return no rows eventually, so when that happens, no exception is raised.

SQL group functions such as AVG and SUM always return a value or a null. So, a SELECT INTO statement that calls a group function will never raise **NO_DATA_FOUND**.

**NOT_LOGGED_ON** is raised if your PL/SQL program issues a database call without being connected to Oracle.

**PROGRAM_ERROR** is raised if PL/SQL has an internal problem.

**ROWTYPE_MISMATCH** is raised if the host cursor variable and PL/SQL cursor variable involved in an assignment have incompatible return types. For example, when you pass an open host cursor variable to a stored subprogram, if the return types of the actual and formal parameters are incompatible, PL/SQL raises **ROWTYPE_MISMATCH**.

**STORAGE_ERROR** is raised if PL/SQL runs out of memory or if memory is corrupted.

**TIMEOUT_ON_RESOURCE** is raised if a timeout occurs while Oracle is waiting for a resource.
**TOO_MANY_ROWS** is raised if a SELECT INTO statement returns more than one row.

**VALUE_ERROR** is raised if an arithmetic, conversion, truncation, or constraint error occurs. For example, when you select a column value into a character variable, if the value is longer than the declared length of the variable, PL/SQL aborts the assignment and raises **VALUE_ERROR**.

In procedural statements, **VALUE_ERROR** is raised if the conversion of a character string to a number fails. For example, the following assignment statement raises **VALUE_ERROR** when PL/SQL tries to convert ‘HALL’ to a number:

```sql
DECLARE
  my_empno NUMBER(4);
  my_ename CHAR(10);
BEGIN
  my_empno := 'HALL';  -- raises **VALUE_ERROR**

In SQL statements, **INVALID_NUMBER** is raised instead.

**ZERO_DIVIDE** is raised if you try to divide a number by zero because the result is undefined.

---

**User–Defined Exceptions**

PL/SQL lets you define exceptions of your own. Unlike predefined exceptions, user–defined exceptions must be declared and must be raised explicitly by **RAISE** statements.

**Declaring Exceptions**

Exceptions can be declared only in the declarative part of a PL/SQL block, subprogram, or package. You declare an exception by introducing its name, followed by the keyword **EXCEPTION**. In the following example, you declare an exception named **past_due**:

```sql
DECLARE
  past_due EXCEPTION;
  acct_num NUMBER(5);
```

Exception and variable declarations are similar. But remember, an exception is an error condition, not an object. Unlike variables, exceptions cannot appear in assignment statements or SQL statements. However, the same scope rules apply to variables and exceptions.
Scope Rules

You cannot declare an exception twice in the same block. You can, however, declare the same exception in two different blocks.

Exceptions declared in a block are considered local to that block and global to all its sub–blocks. Because a block can reference only local or global exceptions, enclosing blocks cannot reference exceptions declared in a sub–block.

If you redeclare a global exception in a sub–block, the local declaration prevails. So, the sub–block cannot reference the global exception unless it was declared in a labeled block, in which case the following syntax is valid:

block_label.exception_name

The next example illustrates the scope rules:

DECLARE
  past_due EXCEPTION;
  acct_num NUMBER;
BEGIN
  ...
  DECLARE  -- sub–block begins
    past_due EXCEPTION;  -- this declaration prevails
    acct_num NUMBER;
  BEGIN
    ...
    IF ... THEN
      RAISE past_due;  -- this is not handled
    END IF;
    ...
  END;  -- sub–block ends
EXCEPTION
  WHEN past_due THEN  -- does not handle RAISED exception
    ...
END;

The enclosing block does not handle the raised exception because the declaration of past_due in the sub–block prevails. Though they share the same name, the two past_due exceptions are different, just as the two acct_num variables share the same name but are different variables. Therefore, the RAISE statement and the WHEN clause refer to different exceptions. To have the enclosing block handle the raised exception, you must remove its declaration from the sub–block or define an OTHERS handler.
Using **EXCEPTION_INIT**

To handle unnamed internal exceptions, you must use the OTHERS handler or the pragma EXCEPTION_INIT. A **pragma** is a compiler directive, which can be thought of as a parenthetical remark to the compiler. Pragmas (also called *pseudoinstructions*) are processed at compile time, not at run time. They do not affect the meaning of a program; they simply convey information to the compiler. For example, in the language Ada, the following pragma tells the compiler to optimize the use of storage space:

```plaintext
pragma OPTIMIZE(SPACE);
```

In PL/SQL, the pragma EXCEPTION_INIT tells the compiler to associate an exception name with an Oracle error number. That allows you to refer to any internal exception by name and to write a specific handler for it.

You code the pragma EXCEPTION_INIT in the declarative part of a PL/SQL block, subprogram, or package using the syntax

```plaintext
PRAGMA EXCEPTION_INIT(exception_name, Oracle_error_number);
```

where `exception_name` is the name of a previously declared exception. The pragma must appear somewhere after the exception declaration in the same declarative part, as shown in the following example:

```plaintext
DECLARE
  insufficient_privileges EXCEPTION;
PRAGMA EXCEPTION_INIT(insufficient_privileges, -1031);
  /* Oracle returns error number -1031 if, for example, */
  /* you try to UPDATE a table for which you have */
  /* only SELECT privileges */
BEGIN
  ...
EXCEPTION
  WHEN insufficient_privileges THEN
    -- handle the error
  ...
END;
```
Package DBMS_STANDARD, which is supplied with Oracle7, provides language facilities that help your application interact with Oracle. For example, the procedure *raise_application_error* lets you issue user-defined error messages from stored subprograms. That way, you can report errors to your application and avoid returning unhandled exceptions.

To call *raise_application_error*, you use the syntax

```sql
raise_application_error(error_number, message[, {TRUE | FALSE}]);
```

where *error_number* is a negative integer in the range –20000 .. –20999 and *message* is a character string up to 2048 bytes long. If the optional third parameter is TRUE, the error is placed on the stack of previous errors. If the parameter is FALSE (the default), the error replaces all previous errors. Package DBMS_STANDARD is an extension of package STANDARD, so you need not qualify references to it.

An application can call *raise_application_error* only from an executing stored subprogram. When called, *raise_application_error* ends the subprogram, rolls back any database changes it made, and returns a user-defined error number and message to the application. The error number and message can be trapped like any Oracle error.

In the following example, you call *raise_application_error* if an employee’s salary is missing:

```sql
CREATE PROCEDURE raise_salary (emp_id NUMBER, increase NUMBER) AS
  current_salary NUMBER;
BEGIN
  SELECT sal INTO current_salary FROM emp
  WHERE empno = emp_id;
  IF current_salary IS NULL THEN
    /* Issue user-defined error message. */
    raise_application_error(-20101, 'Salary is missing');
  ELSE
    UPDATE emp SET sal = current_salary + increase
    WHERE empno = emp_id;
  END IF;
END raise_salary;
```
The calling application gets a PL/SQL exception, which it can process using the error-reporting functions SQLCODE and SQLERRM in an OTHERS handler. Also, it can use the pragma EXCEPTION_INIT to map specific error numbers returned by `raise_application_error` to exceptions of its own, as follows:

```sql
EXEC SQL EXECUTE
  DECLARE
    null_salary EXCEPTION;
    /* Map error number returned by raise_application_error
       to user-defined exception. */
    PRAGMA EXCEPTION_INIT(null_salary, -20101);
BEGIN
  ...  
  raise_salary(:emp_number, :amount);
EXCEPTION
  WHEN null_salary THEN
    INSERT INTO emp_audit VALUES (:emp_number, ...);
  ...
END;
END-EXEC;
```

This technique allows the calling application to handle error conditions in specific exception handlers.

**Redeclaring Predefined Exceptions**

Remember, PL/SQL declares predefined exceptions globally in package STANDARD, so you need not declare them yourself. Redeclaring predefined exceptions is error prone because your local declaration overrides the global declaration.

For example, if you declare an exception named `invalid_number` and then PL/SQL raises the predefined exception INVALID_NUMBER internally, a handler written for INVALID_NUMBER will not catch the internal exception. In such cases, you must use dot notation to specify the predefined exception, as follows:

```sql
EXCEPTION
  WHEN invalid_number OR STANDARD.INVALID_NUMBER THEN
    -- handle the error
    ...
  WHEN OTHERS THEN ...
END;
```
How Exceptions Are Raised

Internal exceptions are raised implicitly by the runtime system, as are user–defined exceptions that you have associated with an Oracle error number using EXCEPTION_INIT. However, other user–defined exceptions must be raised explicitly by RAISE statements.

Using the RAISE Statement

PL/SQL blocks and subprograms should raise an exception only when an error makes it undesirable or impossible to finish processing. You can place RAISE statements for a given exception anywhere within the scope of that exception. In the following example, you alert your PL/SQL block to a user–defined exception named `out_of_stock`:

```plsql
DECLARE
    out_of_stock   EXCEPTION;
    number_on_hand NUMBER(4);
BEGIN
    ...
    IF number_on_hand < 1 THEN
        RAISE out_of_stock;
    END IF;
    ...
EXCEPTION
    WHEN out_of_stock THEN
        -- handle the error
END;
```

You can also raise a predefined exception explicitly. That way, an exception handler written for the predefined exception can process other errors, as the following example shows:

```plsql
DECLARE
    acct_type INTEGER;
    ...
BEGIN
    ...
    IF acct_type NOT IN (1, 2, 3) THEN
        RAISE INVALID_NUMBER;  -- raise predefined exception
    END IF;
    ...
EXCEPTION
    WHEN INVALID_NUMBER THEN
        ROLLBACK;
    ...
END;
```
How Exceptions Propagate

When an exception is raised, if PL/SQL cannot find a handler for it in the current block or subprogram, the exception propagates. That is, the exception reproduces itself in successive enclosing blocks until a handler is found or there are no more blocks to search. In the latter case, PL/SQL returns an unhandled exception error to the host environment.

However, exceptions cannot propagate across remote procedure calls (RPCs). Therefore, a PL/SQL block cannot catch an exception raised by a remote subprogram. For a workaround, see “Using raise_application_error” on page 5–10.

Figure 5–1, Figure 5–2, and Figure 5–3 illustrate the basic propagation rules.

Figure 5–1  Propagation Rules: Example 1
Exception B propagates to the first enclosing block with an appropriate handler.

Exception B is handled, then control passes to the host environment.

Exception C has no handler, so an unhandled exception is returned to the host environment.

Figure 5 – 2 Propagation Rules: Example 2

Figure 5 – 3 Propagation Rules: Example 3
An exception can propagate beyond its scope, that is, beyond the block in which it was declared. Consider the following example:

BEGIN
  ...
  DECLARE  sub-block begins
    past_due EXCEPTION;
  BEGIN
    ...
    IF ... THEN
      RAISE past_due;
    END IF;
  END;
EXCEPTION
  ...
  WHEN OTHERS THEN
    ROLLBACK;
END;

Because the block in which it was declared has no handler for the exception named past_due, it propagates to the enclosing block. But, according to the scope rules, enclosing blocks cannot reference exceptions declared in a sub-block. So, only an OTHERS handler can catch the exception.

**Reraising an Exception**

Sometimes, you want to *reraise* an exception, that is, handle it locally, then pass it to an enclosing block. For example, you might want to rollback a transaction in the current block, then log the error in an enclosing block.

To reraise an exception, simply place a RAISE statement in the local handler, as shown in the following example:

DECLARE
  out_of_balance EXCEPTION;
BEGIN
  ...
  BEGIN  sub-block begins
    ...
    IF ... THEN
      RAISE out_of_balance; -- raise the exception
    END IF;
  END;
EXCEPTION
  WHEN out_of_balance THEN
    -- handle the error
    RAISE;  -- reraise the current exception
    ...
END;  -------------- sub-block ends
EXCEPTION
  WHEN out_of_balance THEN
    -- handle the error differently
    ...
END;

Omitting the exception name in a RAISE statement—allowed only in an
exception handler—reraises the current exception.

---

Handling Raised Exceptions

When an exception is raised, normal execution of your PL/SQL block or
subprogram stops and control transfers to its exception–handling part,
which is formatted as follows:

EXCEPTION
  WHEN exception_name1 THEN  -- handler
    sequence_of_statements1
  WHEN exception_name2 THEN  -- another handler
    sequence_of_statements2
  ...
  WHEN OTHERS THEN           -- optional handler
    sequence_of_statements3
END;

To catch raised exceptions, you must write exception handlers. Each
handler consists of a WHEN clause, which specifies an exception,
followed by a sequence of statements to be executed when that
exception is raised. These statements complete execution of the block or
subprogram; control does not return to where the exception was raised.
In other words, you cannot resume processing where you left off.

The optional OTHERS exception handler, which is always the last
handler in a block or subprogram, acts as the handler for all exceptions
not named specifically. Thus, a block or subprogram can have only one
OTHERS handler.
As the following example shows, use of the OTHERS handler guarantees that no exception will go unhandled:

```sql
EXCEPTION
    WHEN ... THEN
    -- handle the error
    WHEN ... THEN
    -- handle the error
    ...
    WHEN OTHERS THEN
    -- handle all other errors
END;
```

If you want two or more exceptions to execute the same sequence of statements, list the exception names in the WHEN clause, separating them by the keyword OR, as follows:

```sql
EXCEPTION
    WHEN over_limit OR under_limit OR VALUE_ERROR THEN
    -- handle the error
```

If any of the exceptions in the list is raised, the associated sequence of statements is executed. The keyword OTHERS cannot appear in the list of exception names; it must appear by itself. You can have any number of exception handlers, and each handler can associate a list of exceptions with a sequence of statements. However, an exception name can appear only once in the exception–handling part of a PL/SQL block or subprogram.

The usual scoping rules for PL/SQL variables apply, so you can reference local and global variables in an exception handler. However, when an exception is raised inside a cursor FOR loop, the cursor is closed implicitly before the handler is invoked. Therefore, the values of explicit cursor attributes are not available in the handler.

### Exceptions Raised in Declarations

Exceptions can be raised in declarations by faulty initialization expressions. For example, the following declaration raises an exception because the constant `limit` cannot store numbers larger than 999:

```sql
DECLARE
    limit CONSTANT NUMBER(3) := 5000;  -- raises an exception
BEGIN
    ...
EXCEPTION
    WHEN OTHERS THEN  -- cannot catch the exception
    ...
```

Handlers in the current block cannot catch the raised exception because an exception raised in a declaration propagates immediately to the enclosing block.
Exceptions Raised in Handlers

Only one exception at a time can be active in the exception-handling part of a block or subprogram. So, an exception raised inside a handler propagates immediately to the enclosing block, which is searched to find a handler for the newly raised exception. From there on, the exception propagates normally. Consider the following example:

```plsql
EXCEPTION
  WHEN INVALID_NUMBER THEN
    INSERT INTO ... -- might raise DUP_VAL_ON_INDEX
  WHEN DUP_VAL_ON_INDEX THEN -- cannot catch the exception
    ...
END;
```

Branching to or from an Exception Handler

A GOTO statement cannot branch to an exception handler; nor can it branch from an exception handler into the current block. For example, the following GOTO statement is illegal:

```plsql
DECLARE
  pe_ratio NUMBER(3,1);
BEGIN
  DELETE FROM stats WHERE symbol = 'XYZ';
  SELECT price / NVL(earnings, 0) INTO pe_ratio FROM stocks
    WHERE symbol = 'XYZ';
  <<my_label>>
  INSERT INTO stats (symbol, ratio)
    VALUES ('XYZ', pe_ratio);
EXCEPTION
  WHEN ZERO_DIVIDE THEN
    pe_ratio := 0;
    GOTO my_label; -- illegal branch into current block
END;
```

However, a GOTO statement can branch from an exception handler into an enclosing block.

Using SQLCODE and SQLERRM

In an exception handler, you can use the functions SQLCODE and SQLERRM to find out which error occurred and to get the associated error message.

For internal exceptions, SQLCODE returns the number of the Oracle error. The number that SQLCODE returns is negative unless the Oracle error is *no data found*, in which case SQLCODE returns +100. SQLERRM returns the corresponding error message. The message begins with the Oracle error code.
For user-defined exceptions, SQLCODE returns +1 and SQLERRM returns the message

User-Defined Exception

unless you used the pragma EXCEPTION_INIT to associate the exception name with an Oracle error number, in which case SQLCODE returns that error number and SQLERRM returns the corresponding error message. The maximum length of an Oracle error message is 512 characters including the error code, nested messages, and message inserts such as table and column names.

If no exception has been raised, SQLCODE returns zero and SQLERRM returns the message

ORA-0000: normal, successful completion

You can pass an error number to SQLERRM, in which case SQLERRM returns the message associated with that error number. Make sure you pass negative error numbers to SQLERRM. In the following example, you pass positive numbers and so get unwanted results:

DECLARE
    ...
    err_msg VARCHAR2(100);
BEGIN
    ...
    /* Get all Oracle error messages. */
    FOR err_num IN 1..9999 LOOP
        err_msg := SQLERRM(err_num); -- wrong; should be -err_num
        INSERT INTO errors VALUES (err_msg);
    END LOOP;
END;

Passing a positive number to SQLERRM always returns the message

User-Defined Exception

unless you pass +100, in which case SQLERRM returns this message:

ORA-01403: no data found

Passing a zero to SQLERRM always returns the following message:

ORA-0000: normal, successful completion
You cannot use SQLCODE or SQLERRM directly in a SQL statement. For example, the following statement is illegal:

```sql
INSERT INTO errors VALUES (SQLCODE, SQLERRM);
```

Instead, you must assign their values to local variables, then use the variables in the SQL statement, as the following example shows:

```sql
DECLARE
    err_num NUMBER;
    err_msg VARCHAR2(100);
BEGIN
    ...
EXCEPTION
    ... WHEN OTHERS THEN
        err_num := SQLCODE;
        err_msg := SUBSTR(SQLERRM, 1, 100);
        INSERT INTO errors VALUES (err_num, err_msg);
END;
```

The string function SUBSTR ensures that a VALUE_ERROR exception (for truncation) is not raised when you assign the value of SQLERRM to `err_msg`. SQLCODE and SQLERRM are especially useful in the OTHERS exception handler because they tell you which internal exception was raised.

**Unhandled Exceptions**

Remember, if it cannot find a handler for a raised exception, PL/SQL returns an *unhandled exception* error to the host environment, which determines the outcome. For example, in the Oracle Precompilers environment, any database changes made by a failed SQL statement or PL/SQL block are rolled back.

Unhandled exceptions can also affect subprograms. If you exit a subprogram successfully, PL/SQL assigns values to OUT parameters. However, if you exit with an unhandled exception, PL/SQL does not assign values to OUT parameters. Also, if a stored subprogram fails with an unhandled exception, PL/SQL does not roll back database work done by the subprogram.

You can avoid unhandled exceptions by coding an OTHERS handler at the topmost level of every PL/SQL block and subprogram.
Useful Techniques

In this section, you learn two useful techniques: how to continue after an exception is raised and how to retry a transaction.

Continuing after an Exception Is Raised

An exception handler lets you recover from an otherwise “fatal” error before exiting a block. But, when the handler completes, the block terminates. You cannot return to the current block from an exception handler. In the following example, if the SELECT INTO statement raises ZERO_DIVIDE, you cannot resume with the INSERT statement:

```sql
DECLARE
  pe_ratio NUMBER(3,1);
BEGIN
  DELETE FROM stats WHERE symbol = 'XYZ';
  SELECT price / NVL(earnings, 0) INTO pe_ratio FROM stocks
  WHERE symbol = 'XYZ';
  INSERT INTO stats (symbol, ratio) VALUES ('XYZ', pe_ratio);
EXCEPTION
  WHEN ZERO_DIVIDE THEN
    ...
END;

Though PL/SQL does not support continuable exceptions, you can still handle an exception for a statement, then continue with the next statement. Simply place the statement in its own sub–block with its own exception handlers. If an error occurs in the sub–block, a local handler can catch the exception. When the sub–block terminates, the enclosing block continues to execute at the point where the sub–block ends. Consider the following example:

```sql
DECLARE
  pe_ratio NUMBER(3,1);
BEGIN
  DELETE FROM stats WHERE symbol = 'XYZ';
  BEGIN  -- sub–block begins
    SELECT price / NVL(earnings, 0) INTO pe_ratio FROM stocks
    WHERE symbol = 'XYZ';
  EXCEPTION
    WHEN ZERO_DIVIDE THEN
      pe_ratio := 0;
  END;  -- sub–block ends
  INSERT INTO stats (symbol, ratio) VALUES ('XYZ', pe_ratio);
EXCEPTION
  ...
END;

In this example, if the SELECT INTO statement raises a ZERO_DIVIDE exception, the local handler catches it and sets `pe_ratio` to zero. Execution of the handler is complete, so the sub–block terminates, and execution continues with the INSERT statement.
Retrying a Transaction  

After an exception is raised, rather than abandon your transaction, you might want to retry it. The technique you use is simple. First, encase the transaction in a sub-block. Then, place the sub-block inside a loop that repeats the transaction.

Before starting the transaction, you mark a savepoint. If the transaction succeeds, you commit, then exit from the loop. If the transaction fails, control transfers to the exception handler, where you roll back to the savepoint undoing any changes, then try to fix the problem.

Consider the example below. When the exception handler completes, the sub-block terminates, control transfers to the LOOP statement in the enclosing block, the sub-block starts executing again, and the transaction is retried. You might want to use a FOR or WHILE loop to limit the number of tries.

```sql
DECLARE
  name   CHAR(20);
  ans1   CHAR(3);
  ans2   CHAR(3);
  ans3   CHAR(3);
  suffix NUMBER := 1;
BEGIN
  ...
  LOOP  -- could be FOR i IN 1..10 LOOP to allow ten tries
    BEGIN  -- sub-block begins
      SAVEPOINT start_transaction;  -- mark a savepoint
      /* Remove rows from a table of survey results. */
      DELETE FROM results WHERE answer1 = 'NO';
      /* Add a survey respondent’s name and answers. */
      INSERT INTO results VALUES (name, ans1, ans2, ans3);
      -- raises DUP_VAL_ON_INDEX if two respondents
      -- have the same name (because there is a unique
      -- index on the name column)
      COMMIT;
      EXIT;
    EXCEPTION
      WHEN DUP_VAL_ON_INDEX THEN
        ROLLBACK TO start_transaction;  -- undo changes
        suffix := suffix + 1;  -- try to fix
        name := name || TO_CHAR(suffix);  -- problem
        ...
    END;  -- sub-block ends
  END LOOP;
END;
```
This chapter shows you how to use subprograms, which let you name and encapsulate a sequence of statements. Subprograms aid application development by isolating operations. They are like building blocks, which you can use to construct modular, maintainable applications.
What Are Subprograms?

Subprograms are named PL/SQL blocks that can take parameters and be invoked. PL/SQL has two types of subprograms called *procedures* and *functions*. Generally, you use a procedure to perform an action and a function to compute a value.

Like unnamed or *anonymous* PL/SQL blocks, subprograms have a declarative part, an executable part, and an optional exception–handling part. The declarative part contains declarations of types, cursors, constants, variables, exceptions, and nested subprograms. These objects are local and cease to exist when you exit the subprogram. The executable part contains statements that assign values, control execution, and manipulate Oracle data. The exception–handling part contains exception handlers, which deal with exceptions raised during execution.

Consider the following procedure named *debit_account*, which debits a bank account:

```sql
PROCEDURE debit_account (acct_id INTEGER, amount REAL) IS
  old_balance REAL;
  new_balance REAL;
  overdrawn   EXCEPTION;
BEGIN
  SELECT bal INTO old_balance FROM accts
    WHERE acctno = acct_id;
  new_balance := old_balance – amount;
  IF new_balance < 0 THEN
    RAISE overdrawn;
  ELSE
    UPDATE accts SET bal = new_balance
      WHERE acctno = acct_id;
  END IF;
EXCEPTION
  WHEN overdrawn THEN
    ...
END debit_account;
```

When invoked or *called*, this procedure accepts an account number and a debit amount. It uses the account number to select the account balance from the *accts* database table. Then, it uses the debit amount to compute a new balance. If the new balance is less than zero, an exception is raised; otherwise, the bank account is updated.
Advantages of Subprograms

Subprograms provide *extensibility*; that is, they let you tailor the PL/SQL language to suit your needs. For example, if you need a procedure that creates new departments, you can easily write one, as follows:

```sql
PROCEDURE create_dept (new_dname CHAR, new_loc CHAR) IS
  BEGIN
    INSERT INTO dept
      VALUES (deptno_seq.NEXTVAL, new_dname, new_loc);
  END create_dept;
```

Subprograms also provide *modularity*; that is, they let you break a program down into manageable, well-defined logic modules. This supports top-down design and the stepwise refinement approach to problem solving.

Also, subprograms promote *reusability* and *maintainability*. Once validated, a subprogram can be used with confidence in any number of applications. Furthermore, only the subprogram is affected if its definition changes. This simplifies maintenance and enhancement.

Finally, subprograms aid *abstraction*, the mental separation from particulars. To use subprograms, you must know what they do, not how they work. Therefore, you can design applications from the top down without worrying about implementation details. Dummy subprograms (stubs) allow you to defer the definition of procedures and functions until you test and debug the main program.

Procedures

A procedure is a subprogram that performs a specific action. You write procedures using the syntax:

```
PROCEDURE name [(parameter[, parameter, ...])] IS
  [local declarations]
BEGIN
  executable statements
  [EXCEPTION
    exception handlers]
END [name];
```

where *parameter* stands for the following syntax:

```
parameter_name [IN | OUT | IN OUT] datatype [{:= | DEFAULT} expr]
```
You cannot specify a constraint on the datatype. For example, the following declaration of `emp_id` is illegal:

```sql
PROCEDURE ... (emp_id NUMBER(4)) IS -- illegal; should be NUMBER
BEGIN ... END;
```

A procedure has two parts: the specification and the body. The procedure specification begins with the keyword PROCEDURE and ends with the procedure name or a parameter list. Parameter declarations are optional. Procedures that take no parameters are written without parentheses.

The procedure body begins with the keyword IS and ends with the keyword END followed by an optional procedure name. The procedure body has three parts: a declarative part, an executable part, and an optional exception-handling part.

The declarative part contains local declarations, which are placed between the keywords IS and BEGIN. The keyword DECLARE, which introduces declarations in an anonymous PL/SQL block, is not used. The executable part contains statements, which are placed between the keywords BEGIN and EXCEPTION (or END). At least one statement must appear in the executable part of a procedure. The NULL statement meets this requirement. The exception-handling part contains exception handlers, which are placed between the keywords EXCEPTION and END.

Consider the procedure `raise_salary`, which increases the salary of an employee:

```sql
PROCEDURE raise_salary (emp_id INTEGER, increase REAL) IS
    current_salary REAL;
    salary_missing EXCEPTION;
BEGIN
    SELECT sal INTO current_salary FROM emp
    WHERE empno = emp_id;
    IF current_salary IS NULL THEN
        RAISE salary_missing;
    ELSE
        UPDATE emp SET sal = sal + increase
        WHERE empno = emp_id;
    END IF;
EXCEPTION
    WHEN NO_DATA_FOUND THEN
        INSERT INTO emp_audit VALUES (emp_id, 'No such number');
    WHEN salary_missing THEN
        INSERT INTO emp_audit VALUES (emp_id, 'Salary is null');
END raise_salary;
```
When called, this procedure accepts an employee number and a salary increase amount. It uses the employee number to select the current salary from the emp database table. If the employee number is not found or if the current salary is null, an exception is raised. Otherwise, the salary is updated.

A procedure is called as a PL/SQL statement. For example, you might call the procedure `raise_salary` as follows:

```
raise_salary(emp_num, amount);
```

### Functions

A function is a subprogram that computes a value. Functions and procedures are structured alike, except that functions have a RETURN clause. You write functions using the syntax:

```
FUNCTION name [(parameter[, parameter, ...])] RETURN datatype IS
    [local declarations]
BEGIN
    executable statements
    [EXCEPTION
        exception handlers]
END [name];
```

where `parameter` stands for the following syntax:

```
parameter_name [IN | OUT | IN OUT] datatype [{:= | DEFAULT} expr]
```

Remember, you cannot specify a constraint on the datatype.

Like a procedure, a function has two parts: the specification and the body. The function specification begins with the keyword `FUNCTION` and ends with the RETURN clause, which specifies the datatype of the result value. Parameter declarations are optional. Functions that take no parameters are written without parentheses.

The function body begins with the keyword `IS` and ends with the keyword `END` followed by an optional function name. The function body has three parts: a declarative part, an executable part, and an optional exception–handling part.
The declarative part contains local declarations, which are placed between the keywords IS and BEGIN. The keyword DECLARE is not used. The executable part contains statements, which are placed between the keywords BEGIN and EXCEPTION (or END). One or more RETURN statements must appear in the executable part of a function. The exception–handling part contains exception handlers, which are placed between the keywords EXCEPTION and END.

Consider the function sal_ok, which determines if an employee salary is out of range:

```
FUNCTION sal_ok (salary REAL, title REAL) RETURN BOOLEAN IS
    min_sal REAL;
    max_sal REAL;
BEGIN
    SELECT losal, hisal INTO min_sal, max_sal
        FROM sals
        WHERE job = title;
    RETURN (salary >= min_sal) AND (salary <= max_sal);
END sal_ok;
```

When called, this function accepts an employee salary and job title. It uses the job title to select range limits from the sals database table. The function identifier, sal_ok, is set to a Boolean value by the RETURN statement. If the salary is out of range, sal_ok is set to FALSE; otherwise, sal_ok is set to TRUE.

A function is called as part of an expression. For example, the function sal_ok might be called as follows:

```
IF sal_ok(new_sal, new_title) THEN ... 
```

The function identifier acts like a variable whose value depends on the parameters passed to it.

Restriction

Calls to a user–defined stored function can appear in SQL statements only if the function meets certain requirements. See “Calling Stored Functions from SQL Expressions” in Oracle7 Server Application Developer’s Guide.
RETURN Statement

The RETURN statement immediately completes the execution of a subprogram and returns control to the caller. Execution then resumes with the statement following the subprogram call. (Do not confuse the RETURN statement with the RETURN clause, which specifies the datatype of the result value in a function specification.)

A subprogram can contain several RETURN statements, none of which need be the last lexical statement. Executing any of them completes the subprogram immediately. However, it is poor programming practice to have multiple exit points in a subprogram.

In procedures, a RETURN statement cannot contain an expression. The statement simply returns control to the caller before the normal end of the procedure is reached.

However, in functions, a RETURN statement must contain an expression, which is evaluated when the RETURN statement is executed. The resulting value is assigned to the function identifier, which acts like a variable of the type specified in the RETURN clause. Observe how the function balance returns the balance of a specified bank account:

```sql
FUNCTION balance (acct_id INTEGER) RETURN REAL IS
  acct_bal REAL;
BEGIN
  SELECT bal INTO acct_bal FROM accts
  WHERE acctno = acct_id;
  RETURN acct_bal;
END balance;
```

The following example shows that the expression in a function RETURN statement can be arbitrarily complex:

```sql
FUNCTION compound (years NUMBER,
  amount NUMBER,
  rate   NUMBER) RETURN NUMBER IS
BEGIN
  RETURN amount * POWER((rate / 100) + 1, years);
END compound;
```

A function must contain at least one RETURN statement. Otherwise, PL/SQL raises the predefined exception PROGRAM_ERROR at run time.
Declaring Subprograms

You can declare subprograms in any PL/SQL block, subprogram, or package. However, you must declare subprograms at the end of a declarative section after all other program objects. For example, the following procedure declaration is misplaced:

```sql
DECLARE
  PROCEDURE award_bonus (...) IS -- misplaced; must come last
  BEGIN
    ...
  END;
  rating NUMBER;
  CURSOR c1 IS SELECT * FROM emp;
  ...
```

Forward Declarations

PL/SQL requires that you declare an identifier before using it. Therefore, you must declare a subprogram before calling it. For example, the following declaration of procedure `award_bonus` is illegal because `award_bonus` calls procedure `calc_rating`, which is not yet declared when the call is made:

```sql
DECLARE
  PROCEDURE award_bonus ( ...) IS
  BEGIN
    calc_rating( ... ); -- undeclared identifier
    ...
  END;
  PROCEDURE calc_rating ( ... ) IS
  BEGIN
    ...
  END;
  ...
```

In this case, you can solve the problem easily by placing procedure `calc_rating` before procedure `award_bonus`. However, the easy solution does not always work. For example, suppose the procedures are mutually recursive (call each other) or you want to define them in alphabetical order.

PL/SQL solves this problem by providing a special subprogram declaration called a forward declaration. You can use forward declarations to

- define subprograms in logical or alphabetical order
- define mutually recursive subprograms (see “Recursion” on page 6 – 23)
- group subprograms in a package
A forward declaration consists of a subprogram specification terminated by a semicolon. In the following example, the forward declaration advises PL/SQL that the body of procedure `calc_rating` can be found later in the block:

```plsql
DECLARE
    PROCEDURE calc_rating ( ... );  -- forward declaration
...
/* Define subprograms in alphabetical order. */
PROCEDURE award_bonus ( ... ) IS
    BEGIN
        calc_rating( ... );
    ...
END;
PROCEDURE calc_rating ( ... ) IS
    BEGIN
        ...
    END;
...
```

Although the formal parameter list appears in the forward declaration, it must also appear in the subprogram body. You can place the subprogram body anywhere after the forward declaration, but they must appear in the same program unit.

In Packages

Forward declarations also let you group logically related subprograms in a package. The subprogram specifications go in the package specification, and the subprogram bodies go in the package body, where they are invisible to applications. Thus, packages allow you to hide implementation details. An example follows:

```plsql
CREATE PACKAGE emp_actions AS  -- package specification
    PROCEDURE hire_employee (emp_id INTEGER, name VARCHAR2, ...);
    PROCEDURE fire_employee (emp_id INTEGER);
    PROCEDURE raise_salary (emp_id INTEGER, increase REAL);
...
END emp_actions;

CREATE PACKAGE BODY emp_actions AS  -- package body
    PROCEDURE hire_employee (emp_id INTEGER, name VARCHAR2, ...) IS
        BEGIN
            INSERT INTO emp VALUES (empno, ename, ...);
    END hire_employee;
```
PROCEDURE fire_employee (emp_id INTEGER) IS
BEGIN
  DELETE FROM emp
  WHERE empno = emp_id;
END fire_employee;

PROCEDURE raise_salary (emp_id INTEGER, increase REAL) IS
  salary REAL;
BEGIN
  SELECT sal INTO salary FROM emp
  WHERE empno = emp_id;
  ... 
END raise_salary;
...
END emp_actions;

You can define subprograms in a package body without declaring their specifications in the package specification. However, such subprograms can be called only from inside the package. For more information about packages, see Chapter 7.

**Stored Subprograms**

Generally, tools (such as Oracle Forms) that incorporate the PL/SQL engine can store subprograms locally for later, strictly local execution. However, to become available for general use by all tools, subprograms must be stored in an Oracle database.

To create subprograms and store them permanently in an Oracle database, you use the CREATE PROCEDURE and CREATE FUNCTION statements, which you can execute interactively from SQL*Plus or Server Manager. For example, you might create the procedure `fire_employee`, as follows:

```sql
CREATE PROCEDURE fire_employee (emp_id NUMBER) AS
BEGIN
  DELETE FROM emp WHERE empno = emp_id;
END;
```

When creating subprograms, you can use the keyword AS instead of IS in the specification for readability. For more information about creating and using stored subprograms, see *Oracle7 Server Application Developer's Guide*. 
Actual versus Formal Parameters

Subprograms pass information using parameters. The variables or expressions referenced in the parameter list of a subprogram call are actual parameters. For example, the following procedure call lists two actual parameters named `emp_num` and `amount`:

```sql
raise_salary(emp_num, amount);
```

The next procedure call shows that in some cases, expressions can be used as actual parameters:

```sql
raise_salary(emp_num, merit + cola);
```

The variables declared in a subprogram specification and referenced in the subprogram body are formal parameters. For example, the following procedure declares two formal parameters named `emp_id` and `increase`:

```sql
PROCEDURE raise_salary (emp_id INTEGER, increase REAL) IS
    current_salary  REAL;
    ...
BEGIN
    SELECT sal INTO current_salary FROM emp WHERE empno = emp_id;
    ...
    UPDATE emp SET sal = sal + increase WHERE empno = emp_id;
END raise_salary;
```

Though not necessary, it is good programming practice to use different names for actual and formal parameters.

When you call procedure `raise_salary`, the actual parameters are evaluated and the result values are assigned to the corresponding formal parameters. Before assigning the value of an actual parameter to a formal parameter, PL/SQL converts the datatype of the value if necessary. For example, the following call to `raise_salary` is legal:

```sql
raise_salary(emp_num, '2500');
```

The actual parameter and its corresponding formal parameter must have compatible datatypes. For instance, PL/SQL cannot convert between the DATE and REAL datatypes. Also, the result value must be convertible to the new datatype. The following procedure call raises the predefined exception VALUE_ERROR because PL/SQL cannot convert the second actual parameter to a number:

```sql
raise_salary(emp_num, '$2500');  -- note the dollar sign
```

For more information, see “Datatype Conversion” on page 2–16.
Positional and Named Notation

When calling a subprogram, you can write the actual parameters using either positional or named notation. That is, you can indicate the association between an actual and formal parameter by position or name. For example, given the declarations

```plsql
DECLARE
    acct INTEGER;
    amt REAL;
PROCEDURE credit (acctno INTEGER, amount REAL) IS
BEGIN ... END;
```

you can call the procedure `credit` in four logically equivalent ways:

```plsql
BEGIN
    ...
    credit(acct, amt);         -- positional notation
    credit(amount => amt, acctno => acct);  -- named notation
    credit(acctno => acct, amount => amt);  -- named notation
    credit(acct, amount => amt);          -- mixed notation
END;
```

**Positional Notation**

The first procedure call uses positional notation. The PL/SQL compiler associates the first actual parameter, `acct`, with the first formal parameter, `acctno`. And, the compiler associates the second actual parameter, `amt`, with the second formal parameter, `amount`.

**Named Notation**

The second procedure call uses named notation. The arrow (called an association operator) associates the formal parameter to the left of the arrow with the actual parameter to the right of the arrow.

The third procedure call also uses named notation and shows that you can list the parameter pairs in any order. Therefore, you need not know the order in which the formal parameters are listed.

**Mixed Notation**

The fourth procedure call shows that you can mix positional and named notation. In this case, the first parameter uses positional notation, and the second parameter uses named notation. Positional notation must precede named notation. The reverse is not allowed. For example, the following procedure call is illegal:

```plsql
credit(acctno => acct, amt);  -- illegal
```
Parameter Modes

You use parameter modes to define the behavior of formal parameters. The three parameter modes, IN (the default), OUT, and IN OUT, can be used with any subprogram. However, avoid using the OUT and IN OUT modes with functions. The purpose of a function is to take zero or more arguments (actual parameters) and return a single value. It is poor programming practice to have a function return multiple values. Also, functions should be free from side effects, which change the values of variables not local to the subprogram.

IN Mode

An IN parameter lets you pass values to the subprogram being called. Inside the subprogram, an IN parameter acts like a constant. Therefore, it cannot be assigned a value. For example, the following assignment statement causes a compilation error:

```plaintext
PROCEDURE debit_account (acct_id IN INTEGER, amount IN REAL) IS
    minimum_purchase CONSTANT REAL := 10.0;
    service_charge CONSTANT REAL := 0.50;
BEGIN
    ...
    IF amount < minimum_purchase THEN
        amount := amount + service_charge;  -- causes syntax error
    END IF;

    The actual parameter that corresponds to an IN formal parameter can be a constant, literal, initialized variable, or expression.

    Unlike OUT and IN OUT parameters, IN parameters can be initialized to default values. For more information, see “Parameter Default Values” on page 6 – 15.
```

OUT Mode

An OUT parameter lets you return values to the caller of a subprogram. Inside the subprogram, an OUT parameter acts like an uninitialized variable. Therefore, its value cannot be assigned to another variable or reassigned to itself. For instance, the following assignment statement causes a compilation error:

```plaintext
PROCEDURE calc_bonus (emp_id IN INTEGER, bonus OUT REAL) IS
    hire_date DATE;
BEGIN
    SELECT sal * 0.10, hiredate INTO bonus, hire_date FROM emp
        WHERE empno = emp_id;
    IF MONTHS_BETWEEN(SYSDATE, hire_date) > 60 THEN
        bonus := bonus + 500;  -- causes syntax error
    END IF;
```
The actual parameter that corresponds to an OUT formal parameter must be a variable; it cannot be a constant or an expression. For example, the following procedure call is illegal:

```
calc_bonus(7499, salary + commission);  -- causes syntax error
```

An OUT actual parameter can have a value before the subprogram is called. However, the value is lost when you call the subprogram. Inside the subprogram, an OUT formal parameter cannot be used in an expression; the only operation allowed on the parameter is to assign it a value.

Before exiting a subprogram, explicitly assign values to all OUT formal parameters. Otherwise, the values of corresponding actual parameters are indeterminate. If you exit successfully, PL/SQL assigns values to the actual parameters. However, if you exit with an unhandled exception, PL/SQL does not assign values to the actual parameters.

**IN OUT Mode**

An IN OUT parameter lets you pass initial values to the subprogram being called and return updated values to the caller. Inside the subprogram, an IN OUT parameter acts like an initialized variable. Therefore, it can be assigned a value and its value can be assigned to another variable. That means you can use an IN OUT formal parameter as if it were a normal variable. You can change its value or reference the value in any way, as the following example shows:

```
PROCEDURE calc_bonus (emp_id IN INTEGER, bonus IN OUT REAL) IS
  hire_date     DATE;
  bonus_missing EXCEPTION;
BEGIN
  SELECT sal * 0.10, hiredate INTO bonus, hire_date FROM emp
  WHERE emno = emp_id;
  IF bonus IS NULL THEN
    RAISE bonus_missing;
  END IF;
  IF MONTHS_BETWEEN(SYSDATE, hire_date) > 60 THEN
    bonus := bonus + 500;
  END IF;
  ...
END calc_bonus;
```

The actual parameter that corresponds to an IN OUT formal parameter must be a variable; it cannot be a constant or an expression. Table 6 – 1 summarizes all you need to know about the parameter modes.
Parameter Default Values

As the example below shows, you can initialize IN parameters to default values. That way, you can pass different numbers of actual parameters to a subprogram, accepting or overriding the default values as you please. Moreover, you can add new formal parameters without having to change every call to the subprogram.

```sql
PROCEDURE create_dept (  
    new_dname CHAR DEFAULT 'TEMP',  
    new_loc   CHAR DEFAULT 'TEMP') IS
BEGIN  
    INSERT INTO dept  
        VALUES (deptno_seq.NEXTVAL, new_dname, new_loc);
END create_dept;
```

If an actual parameter is not passed, the default value of its corresponding formal parameter is used. Consider the following calls to `create_dept`:

```sql
create_dept;  
create_dept('MARKETING');  
create_dept('MARKETING', 'NEW YORK');
```

The first call passes no actual parameters, so both default values are used. The second call passes one actual parameter, so the default value for `new_loc` is used. The third call passes two actual parameters, so neither default value is used.
Usually, you can use positional notation to override the default values of formal parameters. However, you cannot skip a formal parameter by leaving out its actual parameter. For example, the following call incorrectly associates the actual parameter ‘NEW YORK’ with the formal parameter new_dname:

```
create_dept('NEW YORK');  -- incorrect
```

You cannot solve the problem by leaving a placeholder for the actual parameter. For example, the following call is illegal:

```
create_dept( , 'NEW YORK');  -- illegal
```

In such cases, you must use named notation, as follows:

```
create_dept(new_loc => 'NEW YORK');
```

Also, you cannot assign a null to an uninitialized formal parameter by leaving out its actual parameter. For example, given the declaration

```
DECLARE
  FUNCTION gross_pay (emp_id   IN NUMBER,
                      st_hours IN NUMBER DEFAULT 40,
                      ot_hours IN NUMBER) RETURN REAL IS
  BEGIN
    ...
  END;
END;
```

the following function call does not assign a null to ot_hours:

```
IF gross_pay(emp_num) > max_pay THEN ...  -- illegal
```

Instead, you must pass the null explicitly, as in

```
IF gross_pay(emp_num, ot_hour => NULL) > max_pay THEN ...
```

or you can initialize ot_hours to NULL, as follows:

```
ot_hours IN NUMBER DEFAULT NULL;
```

Finally, when creating a stored subprogram, you cannot use bind variables in the DEFAULT clause. The following SQL*Plus example raises a **bad bind variable** exception because at the time of creation, num is just a placeholder whose value might change:

```
SQL> VARIABLE num NUMBER
SQL> CREATE FUNCTION gross_pay (emp_id IN NUMBER DEFAULT :num, ...
```
Parameter Aliasing

To optimize execution, the PL/SQL compiler can choose different methods of parameter passing (copy or reference) for different parameters in the same subprogram call. When the compiler chooses the copy method, the value of an actual parameter is copied into the subprogram. When the compiler chooses the reference method, the address of an actual parameter is passed to the subprogram.

The easy-to-avoid problem of aliasing occurs when a global variable appears as an actual parameter in a subprogram call and then is referenced within the subprogram. The result is indeterminate because it depends on the method of parameter passing chosen by the compiler. Consider the following example:

```
DECLARE
  rent REAL;
PROCEDURE raise_rent (increase IN OUT REAL) IS
BEGIN
  rent := rent + increase;
  /* At this point, if the compiler passed the address
   of the actual parameter to the subprogram, the same
   variable has two names. Thus, the term ‘aliasing’. */
  ...
END raise_rent;
...
BEGIN ...
  raise_rent(rent);  -- indeterminate
```

Aliasing also occurs when the same actual parameter appears twice in a subprogram call. Unless both formal parameters are IN parameters, the result is indeterminate, as the following example shows:

```
DECLARE
  str VARCHAR2(10);
PROCEDURE reverse (in_str VARCHAR2, out_str OUT VARCHAR2) IS
BEGIN
  /* Reverse order of characters in string here. */
  ...
  /* At this point, whether the value of in_str
   is ‘abcd’ or ‘dcba’ depends on the method of
   parameter passing chosen by the compiler. */
END reverse;
...
BEGIN
  str := ‘abcd’;
  reverse(str, str);  -- indeterminate
```
Overloading

PL/SQL lets you overload subprogram names. That is, you can use the same name for several different subprograms as long as their formal parameters differ in number, order, or datatype family. (Figure 2–1 on page 2–10 shows the datatype families.)

Suppose you want to initialize the first \( n \) rows in two PL/SQL tables that were declared as follows:

```sql
DECLARE
    TYPE DateTabTyp IS TABLE OF DATE
        INDEX BY BINARY_INTEGER;
    TYPE RealTabTyp IS TABLE OF REAL
        INDEX BY BINARY_INTEGER;
    hiredate_tab DateTabTyp;
    sal_tab      RealTabTyp;
END;
```

You might write the following procedure to initialize the PL/SQL table named `hiredate_tab`:

```sql
PROCEDURE initialize (tab OUT DateTabTyp, n INTEGER) IS
    BEGIN
        FOR i IN 1..n LOOP
            tab(i) := SYSDATE;
        END LOOP;
    END initialize;
```

Also, you might write the next procedure to initialize the PL/SQL table named `sal_tab`:

```sql
PROCEDURE initialize (tab OUT RealTabTyp, n INTEGER) IS
    BEGIN
        FOR i IN 1..n LOOP
            tab(i) := 0.0;
        END LOOP;
    END initialize;
```

Because the processing in these two procedures is the same, it is logical to give them the same name.

You can place the two overloaded `initialize` procedures in the same block, subprogram, or package. PL/SQL determines which of the two procedures is being called by checking their formal parameters.
Restrictions

Consider the example below. If you call `initialize` with a `DateTabTyp` parameter, PL/SQL uses the first version of `initialize`. But, if you call `initialize` with a `RealTabTyp` parameter, PL/SQL uses the second version.

```plsql
DECLARE
    TYPE DateTabTyp IS TABLE OF DATE
        INDEX BY BINARY_INTEGER;
    TYPE RealTabTyp IS TABLE OF REAL
        INDEX BY BINARY_INTEGER;
    hiredate_tab  DateTabTyp;
    comm_tab      RealTabTyp;
    indx          BINARY_INTEGER;
    ...
BEGIN
    indx := 50;
    initialize(hiredate_tab, indx);  -- calls first version
    initialize(comm_tab, indx);      -- calls second version
    ...
END;
```

Only local or packaged subprograms can be overloaded. Therefore, you cannot overload standalone subprograms. Also, you cannot overload two subprograms if their formal parameters differ only in name or parameter mode. For example, you cannot overload the following two procedures:

```plsql
PROCEDURE reconcile (acctno IN INTEGER) IS
BEGIN
    ...
END;

PROCEDURE reconcile (acctno OUT INTEGER) IS
BEGIN
    ...
END;
```

Furthermore, you cannot overload two subprograms if their formal parameters differ only in datatype and the different datatypes are in the same family. For instance, you cannot overload the following procedures because the datatypes `INTEGER` and `REAL` are in the same family:

```plsql
PROCEDURE charge_back (amount INTEGER) IS
BEGIN
    ...
END;

PROCEDURE charge_back (amount REAL) IS
BEGIN
    ...
END;
```
Likewise, you cannot overload two subprograms if their formal parameters differ only in subtype and the different subtypes are based on types in the same family. For example, you cannot overload the following procedures because the base types CHAR and LONG are in the same family:

```plsql
DECLARE
    SUBTYPE Delimiter IS CHAR;
    SUBTYPE Text IS LONG;
    ...
    PROCEDURE scan (x Delimiter) IS
    BEGIN ... END;

    PROCEDURE scan (x Text) IS
    BEGIN ... END;
```

Finally, you cannot overload two functions that differ only in return type (the datatype of the result value) even if the types are in different families. For example, you cannot overload the following functions:

```plsql
FUNCTION acct_ok (acct_id INTEGER) RETURN BOOLEAN IS
    BEGIN ... END;

FUNCTION acct_ok (acct_id INTEGER) RETURN INTEGER IS
    BEGIN ... END;
```

**How Calls Are Resolved**

Figure 6 – 1 shows how the PL/SQL compiler resolves subprogram calls. When the compiler encounters a procedure or function call, it tries to find a declaration that matches the call. The compiler searches first in the current scope and then, if necessary, in successive enclosing scopes. The compiler stops searching if it finds one or more subprogram declarations in which the subprogram name matches the name of the called subprogram.

To resolve a call among possibly like–named subprograms at the same level of scope, the compiler must find an *exact* match between the actual and formal parameters. That is, they must match in number, order, and datatype (unless some formal parameters were assigned default values). If no match is found or if multiple matches are found, the compiler generates a syntax error.
compare name of called subprogram with names of any subprograms declared in current scope

match(es) found?

compare actual parameter list in subprogram call with formal parameter list in subprogram declaration(s)

match(es) found?

multiple matches?

resolve call

generate syntax error

go to enclosing scope

enclosing scope?

encounter subprogram call

Figure 6 – 1 How the PL/SQL Compiler Resolves Calls
In the following example, you call the enclosing procedure `swap` from within the function `valid`. However, the compiler generates an error because neither declaration of `swap` within the current scope matches the procedure call:

```
PROCEDURE swap (d1 DATE, d2 DATE) IS
  date1 DATE;
  date2 DATE;
FUNCTION valid (d DATE) RETURN BOOLEAN IS
  PROCEDURE swap (n1 INTEGER, n2 INTEGER) IS
    BEGIN ... END swap;
  PROCEDURE swap (n1 REAL, n2 REAL) IS
    BEGIN ... END swap;
  BEGIN
    ...
    swap(date1, date2);
  END valid;
BEGIN
  ...
END swap;
```

### Avoiding Errors

PL/SQL declares built-in functions globally in package STANDARD. Redeclaring them locally is error prone because your local declaration overrides the global declaration. Consider the following example, in which you declare a function named `sign`, then within the scope of that declaration, try to call the built-in function `SIGN`:

```
DECLARE
  x NUMBER;
...
BEGIN
  DECLARE
    FUNCTION sign (n NUMBER) RETURN NUMBER IS
      BEGIN
        IF n < 0 THEN RETURN -1; ELSE RETURN 1; END IF;
      END;
    BEGIN
      ...
      x := SIGN(0);  -- assigns 0 to x
    END;
    ...
  x := SIGN(0);  -- assigns 0 to x
END;
```

Inside the sub-block, PL/SQL uses your function definition, not the built-in definition. To call the built-in function from inside the sub-block, you must use dot notation, as follows:

```
x := STANDARD.SIGN(0);  -- assigns 0 to x
```
Recursion

Recursion is a powerful technique for simplifying the design of algorithms. Basically, recursion means self-reference. In a recursive mathematical sequence, each term is derived by applying a formula to preceding terms. The Fibonacci sequence (1, 1, 2, 3, 5, 8, 13, 21, ...), which was first used to model the growth of a rabbit colony, is an example. Each term in the sequence (after the second) is the sum of the two terms that immediately precede it.

In a recursive definition, something is defined in terms of simpler versions of itself. Consider the definition of \( n \) factorial (\( n! \)), the product of all integers from 1 to \( n \):

\[
n! = n \times (n-1)!
\]

Recursive Subprograms

A recursive subprogram is one that calls itself. Think of a recursive call as a call to some other subprogram that does the same task as your subprogram. Each recursive call creates a new instance of any objects declared in the subprogram, including parameters, variables, cursors, and exceptions. Likewise, new instances of SQL statements are created at each level in the recursive descent.

There must be at least two paths through a recursive subprogram: one that leads to the recursive call and one that does not. That is, at least one path must lead to a terminating condition. Otherwise, the recursion would (theoretically) go on forever. In practice, if a recursive subprogram strays into infinite regress, PL/SQL eventually runs out of memory and raises the predefined exception STORAGE_ERROR.

An Example

To solve some programming problems, you must repeat a sequence of statements until a condition is met. You can use iteration or recursion to solve such problems. Recursion is appropriate when the problem can be broken down into simpler versions of itself. For example, you can evaluate 3! as follows:

\[
0! = 1 \\
1! = 1 \times 0! = 1 \times 1 = 1 \\
2! = 2 \times 1! = 2 \times 1 = 2 \\
3! = 3 \times 2! = 3 \times 2 = 6
\]
To implement this algorithm, you might write the following recursive function, which returns the factorial of a positive integer:

```plsql
FUNCTION fac (n POSITIVE) RETURN INTEGER IS  -- returns n!
BEGIN
  IF n = 1 THEN  -- terminating condition
    RETURN 1;
  ELSE
    RETURN n * fac(n - 1);  -- recursive call
  END IF;
END fac;
```

At each recursive call, \( n \) is decremented. Eventually, \( n \) becomes 1 and the recursion stops.

**Another Example**

Consider the procedure below, which finds the staff of a given manager. The procedure declares two formal parameters, `mgr_no` and `tier`, which represent the manager’s employee number and a tier in his or her departmental organization. Staff members reporting directly to the manager occupy the first tier. When called, the procedure accepts a value for `mgr_no` but uses the default value of `tier`. For example, you might call the procedure as follows:

```plsql
find_staff(7839);
```

The procedure passes `mgr_no` to a cursor in a cursor FOR loop, which finds staff members at successively lower tiers in the organization. At each recursive call, a new instance of the FOR loop is created and another cursor is opened, but prior cursors stay positioned on the next row in their active sets. When a fetch fails to return a row, the cursor is closed automatically and the FOR loop is exited. Since the recursive call is inside the FOR loop, the recursion stops.

```plsql
PROCEDURE find_staff (mgr_no NUMBER, tier NUMBER := 1) IS
  boss_name  CHAR(10);
  CURSOR c1 (boss_no NUMBER) IS
    SELECT empno, ename FROM emp WHERE mgr = boss_no;
BEGIN
  /* Get manager’s name. */
  SELECT ename INTO boss_name FROM emp WHERE empno = mgr_no;
  IF tier = 1 THEN
    INSERT INTO staff  -- single-column output table
      VALUES (boss_name || ' manages the staff');
  END IF;
END find_staff;
```
/* Find staff members who report directly to manager. */
FOR ee IN c1 (mgr_no) LOOP
  INSERT INTO staff
  VALUES (boss_name || ' manages ' || ee.ename
           || ' on tier ' || to_char(tier));
/* Drop to next tier in organization. */
  find_staff(ee.empno, tier + 1);  -- recursive call
END LOOP;
COMMIT;
END;

Unlike the initial call, each recursive call passes a second actual parameter (the next tier) to the procedure.

The last example illustrates recursion, not the efficient use of set-oriented SQL statements. You might want to compare the performance of the recursive procedure to that of the following SQL statement, which does the same task:

```
INSERT INTO staff
  SELECT PRIOR ename || ' manages ' || ename
           || ' on tier ' || to_char(LEVEL - 1)
  FROM emp
START WITH empno = 7839
CONNECT BY PRIOR empno = mgr;
```

The SQL statement is appreciably faster. However, the procedure is more flexible. For example, a multi-table query cannot contain the CONNECT BY clause. So, unlike the procedure, the SQL statement cannot be modified to do joins. (A join combines rows from two or more database tables.) In addition, a procedure can process data in ways that a single SQL statement cannot.

**Caution**

Be careful where you place a recursive call. If you place it inside a cursor FOR loop or between OPEN and CLOSE statements, another cursor is opened at each call. As a result, your program might exceed the limit set by the Oracle initialization parameter OPEN_CURSORS.
Subprograms are *mutually recursive* if they directly or indirectly call each other. In the example below, the Boolean functions *odd* and *even*, which determine whether a number is odd or even, call each other directly. The forward declaration of *odd* is necessary because *even* calls *odd*, which is not yet declared when the call is made. (See “Forward Declarations” on page 6–8.)

```plsql
FUNCTION odd (n NATURAL) RETURN BOOLEAN;  -- forward declaration

FUNCTION even (n NATURAL) RETURN BOOLEAN IS
BEGIN
  IF n = 0 THEN
    RETURN TRUE;
  ELSE
    RETURN odd(n - 1);  -- mutually recursive call
  END IF;
END even;

FUNCTION odd (n NATURAL) RETURN BOOLEAN IS
BEGIN
  IF n = 0 THEN
    RETURN FALSE;
  ELSE
    RETURN even(n - 1);  -- mutually recursive call
  END IF;
END odd;
```

When a positive integer `n` is passed to *odd* or *even*, the functions call each other by turns. At each call, `n` is decremented. Ultimately, `n` becomes zero and the final call returns TRUE or FALSE. For instance, passing the number 4 to *odd* results in this sequence of calls:

```
odd(4)
even(3)
odd(2)
even(1)
odd(0)  -- returns FALSE
```

On the other hand, passing the number 4 to *even* results in the following sequence of calls:

```
even(4)
odd(3)
even(2)
odd(1)
even(0)  -- returns TRUE
```
Recursion versus Iteration

Unlike iteration, recursion is not essential to PL/SQL programming. Any problem that can be solved using recursion can be solved using iteration. Also, the iterative version of a subprogram is usually easier to design than the recursive version. However, the recursive version is usually simpler, smaller, and therefore easier to debug. Compare the following functions, which compute the $n$th Fibonacci number:

--- recursive version

```plsql
FUNCTION fib (n POSITIVE) RETURN INTEGER IS
BEGIN
  IF (n = 1) OR (n = 2) THEN
    RETURN 1;
  ELSE
    RETURN fib(n - 1) + fib(n - 2);
  END IF;
END fib;
```

--- iterative version

```plsql
FUNCTION fib (n POSITIVE) RETURN INTEGER IS
  pos1 INTEGER := 1;
  pos2 INTEGER := 0;
  cum INTEGER;
BEGIN
  IF (n = 1) OR (n = 2) THEN
    RETURN 1;
  ELSE
    cum := pos1 + pos2;
    FOR i IN 3..n LOOP
      pos2 := pos1;
      pos1 := cum;
      cum := pos1 + pos2;
    END LOOP;
    RETURN cum;
  END IF;
END fib;
```

The recursive version of `fib` is more elegant than the iterative version. However, the iterative version is more efficient; it runs faster and uses less storage. That is because each recursive call requires additional time and memory. As the number of recursive calls gets larger, so does the difference in efficiency. Still, if you expect the number of recursive calls to be small, you might choose the recursive version for its readability.
This chapter shows you how to bundle related PL/SQL programming constructs into a package. The packaged constructs might include a collection of procedures or a pool of type definitions and variable declarations. For example, a Human Resources package might contain hiring and firing procedures. Once written, your general-purpose package is compiled, then stored in an Oracle database, where, like a library unit, its contents can be shared by many applications.
What Is a Package?

A **package** is a database object that groups logically related PL/SQL types, objects, and subprograms. Packages usually have two parts, a specification and a body, although sometimes the body is unnecessary. The **specification** is the interface to your applications; it declares the types, variables, constants, exceptions, cursors, and subprograms available for use. The **body** fully defines cursors and subprograms, and so implements the specification.

Unlike subprograms, packages cannot be called, parameterized, or nested. Still, the format of a package is similar to that of a subprogram:

```sql
CREATE PACKAGE name AS  -- specification (visible part)
   -- public type and object declarations
   -- subprogram specifications
END [name];

CREATE PACKAGE BODY name AS  -- body (hidden part)
   -- private type and object declarations
   -- subprogram bodies
[BEGIN
   -- initialization statements]
END [name];
```

The specification holds **public** declarations, which are visible to your application. The body holds implementation details and **private** declarations, which are hidden from your application. As Figure 7–1 shows, you can think of the specification as an operational interface and of the body as a “black box”:

![Figure 7–1 Package Interface](image)

You can debug, enhance, or replace a package body without changing the interface (package specification) to the package body.
To create packages and store them permanently in an Oracle database, you use the CREATE PACKAGE and CREATE PACKAGE BODY statements, which you can execute interactively from SQL*Plus or Server Manager. For more information, see Oracle7 Server Application Developer’s Guide.

In the example below, you package a record type, a cursor, and two employment procedures. Notice that the procedure hire_employee uses the database sequence empno_seq and the function SYSDATE to insert a new employee number and hire date, respectively.

```sql
CREATE PACKAGE emp_actions AS -- specification
    TYPE EmpRecTyp IS RECORD (emp_id INTEGER, salary REAL);
    CURSOR desc_salary RETURN EmpRecTyp;
    PROCEDURE hire_employee (ename VARCHAR2, job VARCHAR2, mgr NUMBER, sal NUMBER, comm NUMBER, deptno NUMBER);
    PROCEDURE fire_employee (emp_id NUMBER);
END emp_actions;

CREATE PACKAGE BODY emp_actions AS -- body
    CURSOR desc_salary RETURN EmpRecTyp IS
        SELECT empno, sal FROM emp ORDER BY sal DESC;
    PROCEDURE hire_employee (ename VARCHAR2, job VARCHAR2, mgr NUMBER, sal NUMBER, comm NUMBER, deptno NUMBER) IS
        BEGIN
            INSERT INTO emp VALUES (empno_seq.NEXTVAL, ename, job, mgr, SYSDATE, sal, comm, deptno);
        END hire_employee;
    PROCEDURE fire_employee (emp_id NUMBER) IS
        BEGIN
            DELETE FROM emp WHERE empno = emp_id;
        END fire_employee;
END emp_actions;
```

Only the declarations in the package specification are visible and accessible to applications. Implementation details in the package body are hidden and inaccessible. So, you can change the body (implementation) without having to recompile calling programs.
Advantages of Packages

Packages offer several advantages: modularity, easier application design, information hiding, added functionality, and better performance.

Modularity

Packages let you encapsulate logically related types, objects, and subprograms in a named PL/SQL module. Each package is easy to understand, and the interfaces between packages are simple, clear, and well defined. This aids application development.

Easier Application Design

When designing an application, all you need initially is the interface information in the package specifications. You can code and compile a specification without its body. Once the specification has been compiled, stored subprograms that reference the package can be compiled as well. You need not define the package bodies fully until you are ready to complete the application.

Information Hiding

With packages, you can specify which types, objects, and subprograms are public (visible and accessible) or private (hidden and inaccessible). For example, if a package contains four subprograms, three might be public and one private. The package hides the definition of the private subprogram so that only the package (not your application) is affected if the definition changes. This simplifies maintenance and enhancement. Also, by hiding implementation details from users, you protect the integrity of the package.

Added Functionality

Packaged public variables and cursors persist for the duration of a session. So, they can be shared by all subprograms that execute in the environment. Also, they allow you to maintain data across transactions without having to store it in the database.

Better Performance

When you call a packaged subprogram for the first time, the whole package is loaded into memory. Therefore, subsequent calls to related subprograms in the package require no disk I/O.

In addition, packages stop cascading dependencies and so avoid unnecessary recompiling. For example, if you change the definition of a standalone function, Oracle must recompile all stored subprograms that call the function. However, if you change the definition of a packaged function, Oracle need not recompile the calling subprograms because they do not depend on the package body.
The Package Specification

The package specification contains public declarations. The scope of these declarations is local to your database schema and global to the package. So, the declared objects are accessible from your application and from anywhere in the package. Figure 7 – 2 illustrates the scoping.

![Figure 7 – 2 Package Scope](image)

The specification lists the package resources available to applications. All the information your application needs to use the resources is in the specification. For example, the following declaration shows that the function named fac takes one argument of type INTEGER and returns a value of type INTEGER:

```
FUNCTION fac (n INTEGER) RETURN INTEGER;  -- returns n!
```

That is all the information you need to call the function. You need not consider the underlying implementation of fac (whether it is iterative or recursive, for example).

Only subprograms and cursors have an underlying implementation or definition. So, if a specification declares only types, constants, variables, and exceptions, the package body is unnecessary. Consider the following bodiless package:

```
-- a bodiless package
CREATE PACKAGE trans_data AS
  TYPE TimeTyp IS RECORD (
    minute SMALLINT,
    hour   SMALLINT);
```
TYPE TransTyp IS RECORD (
  category VARCHAR2,
  account INTEGER,
  amount REAL,
  time TimeTyp);
minimum_balance CONSTANT REAL := 10.00;
number_processed INTEGER;
insufficient_funds EXCEPTION;
END trans_data;

The package trans_data needs no body because types, constants,
variables, and exceptions do not have an underlying implementation.
Such packages let you define global variables—usable by subprograms
and database triggers—that persist throughout a session.

Referencing Package Contents

To reference the types, objects, and subprograms declared within a
package specification, you use dot notation, as follows:

package_name.type_name
package_name.object_name
package_name.subprogram_name

You can reference package contents from a database trigger, a stored
subprogram, an Oracle Precompiler application, an OCI application, or
an Oracle tool such as SQL*Plus. For example, you might call the
packaged procedure hire_employee from SQL*Plus, as follows:

SQL> EXECUTE emp.actions.hire_employee('TATE', 'CLERK',...);

In the following example, you call the same procedure from an
anonymous PL/SQL block embedded in a Pro*C program:

EXEC SQL EXECUTE
BEGIN
  emp_actions.hire_employee(:name, :title, ...);
END;
END–EXEC;

The actual parameters name and title are host variables.

Restriction

You cannot reference remote packaged variables directly or indirectly.
For example, you cannot call the following procedure remotely because
it references a packaged variable in a parameter initialization clause:

CREATE PACKAGE random AS
  seed NUMBER;
  PROCEDURE initialize (starter IN NUMBER := seed, ...);
  ...
END random;
The Package Body

The package body implements the package specification. That is, the package body contains the definition of every cursor and subprogram declared in the package specification. Keep in mind that subprograms defined in a package body are accessible outside the package only if their specifications also appear in the package specification.

To match subprogram specifications and bodies, PL/SQL does a token–by–token comparison of their headers. So, except for white space, the headers must match word for word. Otherwise, PL/SQL raises an exception, as the following example shows:

```sql
CREATE PACKAGE emp_actions AS
  PROCEDURE calc_bonus (date_hired emp.hiredate%TYPE, ...);
END emp_actions;
CREATE PACKAGE BODY emp_actions AS
  PROCEDURE calc_bonus (date_hired DATE, ...) IS
  -- parameter declaration raises an exception because 'DATE'
  -- does not match 'emp.hiredate%TYPE' word for word
  BEGIN
  ...
  END calc_bonus;
END emp_actions;
```

The package body can also contain private declarations, which define types and objects necessary for the internal workings of the package. The scope of these declarations is local to the package body. Therefore, the declared types and objects are inaccessible except from within the package body. Unlike a package specification, the declarative part of a package body can contain subprogram bodies.

Following the declarative part of a package body is the optional initialization part, which typically holds statements that initialize some of the variables previously declared in the package.

The initialization part of a package plays a minor role because, unlike subprograms, a package cannot be called or passed parameters. As a result, the initialization part of a package is run only once, the first time you reference the package.
Consider the package below named `emp_actions`. The package specification declares the following types, objects, and subprograms:

- types `EmpRecTyp` and `DeptRecTyp`
- cursor `desc_salary`
- exception `salary_missing`
- functions `hire_employee`, `nth_highest_salary`, and `rank`
- procedures `fire_employee` and `raise_salary`

After writing the package, you can develop applications that reference its types, call its subprograms, use its cursor, and raise its exception. When you create the package, it is stored in an Oracle database for general use.

```sql
CREATE PACKAGE emp_actions AS
/* Declare externally visible types, cursor, exception. */
TYPE EmpRecTyp IS RECORD (emp_id INTEGER, salary REAL);
TYPE DeptRecTyp IS RECORD (dept_id INTEGER, location VARCHAR2);
CURSOR desc_salary RETURN EmpRecTyp;
salary_missing EXCEPTION;

/* Declare externally callable subprograms. */
FUNCTION hire_employee (ename VARCHAR2, job VARCHAR2, mgr NUMBER, sal NUMBER, comm NUMBER, deptno NUMBER) RETURN INTEGER;
PROCEDURE fire_employee (emp_id INTEGER);
PROCEDURE raise_salary (emp_id INTEGER, increase NUMBER);
FUNCTION nth_highest_salary (n INTEGER) RETURN EmpRecTyp;
END emp_actions;

PACKAGE BODY emp_actions IS
  number_hired INTEGER; -- visible only in this package

  /* Fully define cursor specified in package. */
  CURSOR desc_salary RETURN EmpRecTyp IS
    SELECT empno, sal FROM emp ORDER BY sal DESC;

  /* Fully define subprograms specified in package. */
  FUNCTION hire_employee (ename VARCHAR2, job VARCHAR2, mgr NUMBER,
```
DECLARE
  sal    NUMBER,
  comm   NUMBER,
  deptno NUMBER) RETURN INTEGER IS
  new_empno  INTEGER;
BEGIN
  SELECT empno_seq.NEXTVAL INTO new_empno FROM dual;
  INSERT INTO emp VALUES (new_empno, ename, job,
                         mgr, SYSDATE, sal, comm, deptno);
  number_hired := number_hired + 1;
  RETURN new_empno;
END hire_employee;

PROCEDURE fire_employee (emp_id INTEGER) IS
BEGIN
  DELETE FROM emp WHERE empno = emp_id;
END fire_employee;

PROCEDURE raise_salary (emp_id INTEGER, increase NUMBER) IS
  current_salary NUMBER;
BEGIN
  SELECT sal INTO current_salary FROM emp
  WHERE empno = emp_id;
  IF current_salary IS NULL THEN
    RAISE salary_missing;
  ELSE
    UPDATE emp SET sal = sal + increase
    WHERE empno = emp_id;
  END IF;
END raise_salary;

FUNCTION nth_highest_salary (n INTEGER) RETURN EmpRecTyp IS
  emp_rec  EmpRecTyp;
BEGIN
  OPEN desc_salary;
  FOR i IN 1..n LOOP
    FETCH desc_salary INTO emp_rec;
  END LOOP;
  CLOSE desc_salary;
  RETURN emp_rec;
END nth_highest_salary;

FUNCTION rank (emp_id INTEGER, job_title VARCHAR2) RETURN INTEGER IS
BEGIN
  RETURN INTEGER IS
  /* Define local function, available only in package. */
  FUNCTION rank (emp_id INTEGER, job_title VARCHAR2)
  RETURN INTEGER IS
  /* Return rank (highest = 1) of employee in a given
  job classification based on performance rating. */
  head_count INTEGER;
  score      NUMBER;
  RETURN INTEGER IS
BEGIN
    SELECT COUNT(*) INTO head_count FROM emp
    WHERE job = job_title;
    SELECT rating INTO score FROM reviews
    WHERE empno = emp_id;
    score := score / 100;  -- maximum score is 100
    RETURN (head_count + 1) - ROUND(head_count * score);
END rank;

BEGIN  -- initialization part starts here
    INSERT INTO emp_audit VALUES (SYSDATE, USER, 'EMP_ACTIONS');
    number_hired := 0;
END emp_actions;

Remember, the initialization part of a package is run just once, the first

time you reference the package. So, in the last example, only one row is

inserted into the database table emp_audit. Likewise, the variable

number_hired is initialized only once.

Every time the procedure hire_employee is called, the variable

number_hired is updated. However, the count kept by number_hired is

session specific. That is, the count reflects the number of new employees

processed by one user, not the number processed by all users.

In the next example, you package some typical bank transactions.
Assume that debit and credit transactions are entered after business
hours via automatic teller machines, then applied to accounts the
next morning.

PACKAGE bank_transactions IS
    /* Declare externally visible constant. */
    minimum_balance  CONSTANT NUMBER := 100.00;

    /* Declare externally callable procedures. */
    PROCEDURE apply_transactions;
    PROCEDURE enter_transaction (
        acct   NUMBER,
        kind   CHAR,
        amount NUMBER);
END bank_transactions;

PACKAGE BODY bank_transactions IS
    /* Declare global variable to hold transaction status. */
    new_status  VARCHAR2(70) := 'Unknown';

    /* Use forward declarations because apply_transactions
calls credit_account and debit_account, which are not
yet declared when the calls are made. */
    PROCEDURE credit_account (acct NUMBER, credit REAL);
    PROCEDURE debit_account (acct NUMBER, debit REAL);
PROCEDURE apply_transactions IS
CURSOR trans_cursor IS
    SELECT acct_id, kind, amount FROM transactions
    WHERE status = 'Pending'
    ORDER BY time_tag
    FOR UPDATE OF status;  -- to lock rows
BEGIN
    FOR trans IN trans_cursor LOOP
        IF trans.kind = 'D' THEN
            debit_account(trans.acct_id, trans.amount);
        ELSIF trans.kind = 'C' THEN
            credit_account(trans.acct_id, trans.amount);
        ELSE
            new_status := 'Rejected';
        END IF;
        UPDATE transactions SET status = new_status
        WHERE CURRENT OF trans_cursor;
    END LOOP;
END apply_transactions;

PROCEDURE enter_transaction (acct   NUMBER, kind   CHAR, amount NUMBER) IS
BEGIN
    INSERT INTO transactions
    VALUES (acct, kind, amount, 'Pending', SYSDATE);
END enter_transaction;

PROCEDURE do_journal_entry (acct    NUMBER, kind     CHAR, new_bal NUMBER) IS
BEGIN
    INSERT INTO journal
    VALUES (acct, kind, new_bal, sysdate);
    IF kind = 'D' THEN
        new_status := 'Debit applied';
    ELSE
        new_status := 'Credit applied';
    END IF;
END do_journal_entry;
PROCEDURE credit_account (acct NUMBER, credit REAL) IS
/* Credit account unless account number is bad. */
old_balance NUMBER;
new_balance NUMBER;
BEGIN
SELECT balance INTO old_balance FROM accounts
    WHERE acct_id = acct
    FOR UPDATE OF balance; -- to lock the row
new_balance := old_balance + credit;
UPDATE accounts SET balance = new_balance
    WHERE acct_id = acct;
do_journal_entry(acct, 'C', new_balance);
EXCEPTION
WHEN NO_DATA_FOUND THEN
    new_status := 'Bad account number';
WHEN OTHERS THEN
    new_status := SUBSTR(SQLERRM,1,70);
END credit_account;

PROCEDURE debit_account (acct NUMBER, debit REAL) IS
/* Debit account unless account number is bad or account has insufficient funds. */
old_balance NUMBER;
new_balance NUMBER;
insufficient_funds EXCEPTION;
BEGIN
SELECT balance INTO old_balance FROM accounts
    WHERE acct_id = acct
    FOR UPDATE OF balance; -- to lock the row
new_balance := old_balance – debit;
IF new_balance >= minimum_balance THEN
    UPDATE accounts SET balance = new_balance
        WHERE acct_id = acct;
do_journal_entry(acct, 'D', new_balance);
ELSE
    RAISE insufficient_funds;
END IF;
EXCEPTION
WHEN NO_DATA_FOUND THEN
    new_status := 'Bad account number';
WHEN insufficient_funds THEN
    new_status := 'Insufficient funds';
WHEN OTHERS THEN
    new_status := SUBSTR(SQLERRM,1,70);
END debit_account;
END bank_transactions;

In this package, the initialization part is not used.
Private versus Public Objects

Look again at the package `emp_actions`. The package body declares a variable named `number_hired`, which is initialized to zero. Unlike items declared in the specification of `emp_actions`, items declared in the body are restricted to use within the package. Therefore, PL/SQL code outside the package cannot reference the variable `number_hired`. Such items are termed `private`.

However, items declared in the specification of `emp_actions` such as the exception `salary_missing` are visible outside the package. Therefore, any PL/SQL code can reference the exception `salary_missing`. Such items are termed `public`.

When you must maintain items throughout a session or across transactions, place them in the declarative part of the package body. For example, the value of `number_hired` is retained between calls to `hire_employee`. Remember, however, that the value of `number_hired` is session specific.

If you must also make the items public, place them in the package specification. For example, the constant `minimum_balance` declared in the specification of the package `bank_transactions` is available for general use.

Note: When you call a packaged subprogram remotely, the whole package is reinstated and its previous state is lost.

Overloading

Recall from Chapter 6 that PL/SQL allows two or more packaged subprograms to have the same name. This option is useful when you want a subprogram to accept parameters that have different datatypes. For example, the following package defines two procedures named `journalize`:

```plsql
CREATE PACKAGE journal_entries AS
  PROCEDURE journalize (amount NUMBER, trans_date VARCHAR2);
  PROCEDURE journalize (amount NUMBER, trans_date NUMBER);
END journal_entries;

CREATE PACKAGE BODY journal_entries AS
  PROCEDURE journalize (amount NUMBER, trans_date VARCHAR2) IS
    BEGIN
      INSERT INTO journal
      VALUES (amount, TO_DATE(trans_date, 'DD-MON-YYYY'));
    END journalize;
```
PROCEDURE journalize (amount NUMBER, trans_date NUMBER) IS
BEGIN
    INSERT INTO journal
    VALUES (amount, TO_DATE(trans_date, 'J'));
END journalize;
END journal_entries;

The first procedure accepts \textit{trans\_date} as a character string, while the second procedure accepts it as a number (the Julian day). Yet, each procedure handles the data appropriately.

### Package STANDARD

A package named STANDARD defines the PL/SQL environment. The package specification globally declares types, exceptions, and subprograms, which are available automatically to every PL/SQL program. For example, package STANDARD declares the following built-in function named ABS, which returns the absolute value of its argument:

FUNCTION ABS (n NUMBER) RETURN NUMBER;

The contents of package STANDARD are directly visible to applications. So, you can call ABS from a database trigger, a stored subprogram, an Oracle Precompiler application, an OCI application, and various Oracle tools including Oracle Forms, Oracle Reports, and SQL*Plus.

If you redeclare ABS in a PL/SQL program, your local declaration overrides the global declaration. However, you can still call the built-in function by using dot notation, as follows:

... STANDARD.ABS(x) ...

Most built-in functions are overloaded. For example, package STANDARD contains the following declarations:

FUNCTION TO_CHAR (right DATE) RETURN VARCHAR2;
FUNCTION TO_CHAR (left NUMBER) RETURN VARCHAR2;
FUNCTION TO_CHAR (left DATE, right VARCHAR2) RETURN VARCHAR2;
FUNCTION TO_CHAR (left NUMBER, right VARCHAR2) RETURN VARCHAR2;

PL/SQL resolves a call to TO\_CHAR by matching the number and datatypes of the formal and actual parameters.
Product-specific Packages

Oracle7 and various Oracle tools are supplied with product-specific packages that help you build PL/SQL-based applications. For example, Oracle7 is supplied with the packages DBMS_STANDARD, DBMS_SQL, DBMS_ALERT, DBMS_OUTPUT, DBMS_PIPE, and others.

Package DBMS_STANDARD provides language facilities that help your application interact with Oracle. For instance, a procedure named `raise_application_error` lets you issue user-defined error messages. That way, you can report errors to an application and avoid returning unhandled exceptions. For an example, see “Using `raise_application_error`” on page 5 – 10.

Package DBMS_SQL allows PL/SQL to execute SQL data definition and data manipulation statements dynamically at run time. For an example, see “Using DDL and Dynamic SQL” on page 4 – 8.

Package DBMS_ALERT lets you use database triggers to alert an application when specific database values change. The alerts are transaction based and asynchronous (that is, they operate independently of any timing mechanism). For example, a company might use this package to update the value of its investment portfolio as new stock and bond quotes arrive.

Package DBMS_OUTPUT enables you to display output from PL/SQL blocks and subprograms, which makes it easier to test and debug them. The `put_line` procedure outputs information to a buffer in the SGA. You display the information by calling the procedure `get_line` or by using the command `SET SERVEROUTPUT ON` in SQL*Plus or Server Manager. For an example, see “Displaying Output” on page 8 – 4.

Package DBMS_PIPE allows different sessions to communicate over named pipes. (A pipe is an area of memory used by one process to pass information to another.) You can use the procedures `pack_message` and `send_message` to pack a message into a pipe, then send it to another session in the same instance. At the other end of the pipe, you can use the procedures `receive_message` and `unpack_message` to receive and unpack (read) the message. Named pipes are useful in many ways. For example, you can write routines in C that allow external servers to collect information, then send it through pipes to procedures stored in an Oracle database.

For more information about these packages, see Oracle7 Server Application Developer’s Guide.
Guidelines

When writing packages, keep them as general as possible so they can be reused in future applications. Avoid writing packages that duplicate some feature already provided by Oracle.

Package specifications reflect the design of your application. So, define them before the package bodies. Place in a specification only the types, objects, and subprograms that must be visible to users of the package. That way, other developers cannot misuse the package by basing their code on irrelevant implementation details.

To reduce the need for recompiling when code is changed, place as few items as possible in a package specification. Changes to a package body do not require Oracle to recompile dependent procedures. However, changes to a package specification require Oracle to recompile every stored subprogram that references the package.
Every tool carries with it the spirit by which it was created.

Werner Heisenberg

You can use PL/SQL with a variety of application development tools. This chapter shows you how to use PL/SQL in the SQL*Plus, Oracle Precompiler, and OCI environments.
SQL*Plus Environment

After entering the SQL*Plus environment, you can use PL/SQL in several ways:

- input and store a PL/SQL block
- input and run a PL/SQL block
- create a script containing PL/SQL blocks
- load and run a script containing PL/SQL blocks
- call a stored subprogram

Inputting an Anonymous Block

Every PL/SQL block begins with the reserved word DECLARE or, if the block has no declarative part, with the reserved word BEGIN. Inputting either reserved word at the SQL*Plus prompt (SQL>) signals SQL*Plus to:

- clear the SQL buffer
- enter INPUT mode
- ignore semicolons (the SQL statement terminator)

SQL*Plus expects you to input an unlabeled PL/SQL block, so you cannot start with a block label.

You input the PL/SQL block line by line. Ending the block with a period (.) on a line by itself stores the block in the SQL buffer.

You can save your PL/SQL block in a script file as follows:

```
SQL> SAVE <filename>
```

If you want to edit the file, you can use the SQL*Plus line editor. For instructions, see SQL*Plus User’s Guide and Reference. After editing the file, you can save it again as follows:

```
SQL> SAVE <filename> REPLACE
```

Executing an Anonymous Block

After inputting a PL/SQL block, you need not end it with a period. Ending the block with a slash (/) on a line by itself stores the block in the SQL buffer, then runs the block. Once it is stored in the SQL buffer, you can run the PL/SQL block again, as follows:

```
SQL> RUN  or  SQL> /
```

When the block is finished running, you are returned to the SQL*Plus prompt. The SQL buffer is not cleared until you start inputting the next SQL statement or PL/SQL block.
Creating a Script

You can use your favorite editor to create text files containing PL/SQL blocks. Although SQL*Plus statements are not allowed in a PL/SQL block, you can intermix them with PL/SQL blocks in a text file. In the example below, a PL/SQL block is intermixed with SQL*Plus statements that set up and display a report. Note that a slash (/) must follow every PL/SQL block.

```
CLEAR BREAKS;
CLEAR COLUMNS;
COLUMN ENAME HEADING NAME;
TTITLE 'CLERICAL STAFF';
DECLARE
  avg_sal  NUMBER(7,2);
BEGIN
  SELECT AVG(sal) INTO avg_sal FROM emp;
  IF avg_sal < 1500 THEN
    UPDATE emp SET sal = sal * 1.05 WHERE job = 'CLERK';
  END IF;
END;
/
SELECT ENAME, SAL FROM EMP WHERE JOB = 'CLERK';
```

The two CLEAR statements get rid of any settings left over from a previous report. The COLUMN statement changes the ENAME column heading to NAME. The TTITLE statement specifies a title that appears at the top of each page in the report. The slash following END executes the PL/SQL block.

Loading and Running a Script

After invoking SQL*Plus, you can load a script into the SQL buffer, as follows:

```
SQL> GET <filename>
```

Once it is stored in the SQL buffer, you can run the script using the RUN command or a slash. If you prefer, you can load and run the script in one step, as follows:

```
SQL> START <filename>  OR  SQL> @$filename
```

Your PL/SQL block can take advantage of the SQL*Plus substitution variable feature. Before running a script, SQL*Plus prompts for the value of any variable prefixed with an ampersand (&). In the following example, SQL*Plus prompts for the value of `num`:

```
SQL> BEGIN
  2   FOR i IN 1..&num LOOP
  3     ...
  9   /
Enter value for num:
```
Calling Stored Subprograms

From SQL*Plus, you can call standalone and packaged subprograms stored in a local or remote database. For example, you might call the local standalone procedure `create_dept`, as follows:

```sql
SQL> EXECUTE create_dept('ADVERTISING', 'NEW YORK');
```

This call is equivalent to the following call issued from an anonymous PL/SQL block:

```sql
SQL> BEGIN create_dept('ADVERTISING', 'NEW YORK'); END;
```

In the next example, you use the database link `newyork` to call the remote stored procedure `raise_salary`:

```sql
SQL> EXECUTE raise_salary@newyork(7499, 1500);
```

You can create synonyms to provide location transparency for remote standalone procedures.

Displaying Output

Currently, PL/SQL does not support I/O. However, the package `DBMS_OUTPUT` (supplied with Oracle7) allows you to display output from PL/SQL blocks and subprograms, which makes it easier to test and debug them. The procedure `put_line` lets you output information to a buffer. The SQL*Plus command `SET SERVEROUTPUT ON` lets you display the information. For example, suppose you create the following stored procedure:

```sql
CREATE PROCEDURE calc_payroll (payroll IN OUT REAL) AS
  CURSOR c1 IS SELECT sal, comm FROM emp;
BEGIN
  payroll := 0;
  FOR c1rec IN c1 LOOP
    c1rec.comm := NVL(c1rec.comm, 0);
    payroll := payroll + c1rec.sal + c1rec.comm;
  END LOOP;
/* Display debug info. */
dbms_output.put_line('payroll: ' || TO_CHAR(payroll));
END calc_payroll;
```

When you issue the following commands, SQL*Plus displays the value of `payroll` calculated by the procedure:

```sql
SQL> SET SERVEROUTPUT ON
SQL> VARIABLE num NUMBER
SQL> EXECUTE calc_payroll(:num);
```

For more information about package `DBMS_OUTPUT`, see `Oracle7 Server Application Developer’s Guide`. 
Oracle Precompiler Environment

The Oracle Precompilers allow you to embed PL/SQL blocks within programs written in any of the following high-level languages: Ada, C, COBOL, FORTRAN, Pascal, and PL/I. Such programs and languages are called host programs and host languages, respectively.

After writing a program, you precompile the source file. The precompiler checks the program for syntax errors, then generates a modified source file, which can be compiled, linked, and executed in the usual way.

Embedding PL/SQL Blocks

You can embed a PL/SQL block wherever you can embed a SQL statement; the precompiler treats them alike. To embed a PL/SQL block in your host program, you must place the block between the keywords EXEC SQL EXECUTE and END-EXEC, as follows:

```
EXEC SQL EXECUTE
BEGIN
...
END;
END-EXEC;
```

Be sure to follow the keyword END-EXEC with the host-language statement terminator.

Using Host Variables

You use host variables to pass values and status codes back and forth between a host program and an embedded PL/SQL block. You declare host variables in the program Declare Section using regular host language syntax. Inside a PL/SQL block, the scope of host variables is global.

Both the host program and the PL/SQL block can set and reference the value of a host variable. The value of an input host variable is set by the host program and referenced by Oracle. Conversely, the value of an output host variable is set by Oracle and referenced by the host program.

All references to host variables in a PL/SQL block must be prefixed with a colon. That way, the precompiler can tell host variables from PL/SQL variables and database objects.

Some Examples

The Pro*C program below illustrates the use of host variables in a PL/SQL block. The program prompts the user for the name of an employee, then passes the name to an embedded PL/SQL block, which uses the name to query an Oracle database. Finally, the results of the query are passed back to the host program, which displays them.
-- available online in file EXAMP9
#include <stdio.h>

EXEC SQL BEGIN DECLARE SECTION;
  VARCHAR  empname[11];
  VARCHAR  jobtype[9];
  VARCHAR  hired[9];
  int      salary;

printf("Hired on: %s\n", hired.arr);
printf("    %d people have served longer\n", served_longer);
printf("Salary is: %d\n", salary);
printf("    %d people have a higher salary\n", higher_sal);
printf("Department number is: %d\n", dept);
printf("    %d people in the department\n", total_in_dept);
} /* End of loop */
} /* End of function */

void sqlerror()
{
  /* Avoid infinite loop if rollback causes an error */
  EXEC SQL WHENEVER SQLERROR CONTINUE;
  printf("\nOracle error detected:\n");
  /* Print error message and disconnect from Oracle */
  printf("\n%.70s\n", sqlca.sqlerrm.sqlerrmc);
  EXEC SQL ROLLBACK WORK RELEASE;
  exit(1);
}

Notice that the host variable empname is assigned a value before the
PL/SQL block is entered and that the other host variables are assigned
values inside the block. When necessary, Oracle converts between its
internal datatypes and standard host-language datatypes.
The next Pro*C example shows how two PL/SQL banking transactions might be implemented:

#include <stdio.h>
EXEC SQL BEGIN DECLARE SECTION;
  int acct, amount;
  VARCHAR tran_type[10];
  VARCHAR status[65];
  VARCHAR uid[20];
  VARCHAR pwd[20];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLCA;

    EXEC SQL ROLLBACK WORK RELEASE;
    exit(1);
}

Using Indicator Variables

You can associate any host variable with an optional indicator variable. An *indicator variable* is an integer variable that indicates the value or condition of a host variable. You use indicator variables to assign nulls to input host variables and to detect nulls or truncated values in output host variables.

For input host variables, the values your program can assign to an indicator variable have the following meanings:

-1 Ignoring the value of the host variable, Oracle will assign a null to the database column.

>= 0 Oracle will assign the value of the host variable to the database column.

For output host variables, the values Oracle can assign to an indicator variable have the following meanings:

-2 Oracle assigned a truncated column value to the host variable but could not store the original length of the column value in the indicator variable because the number was too large.

-1 The database column contains a null, so the value of the host variable is indeterminate.

0 Oracle assigned an intact column value to the host variable.

> 0 Oracle assigned a truncated column value to the host variable and stored the original length of the column value in the indicator variable.

An indicator variable must be defined in the Declare Section as a 2-byte integer and, in SQL statements, must be prefixed with a colon and appended to its host variable unless you use the keyword INDICATOR, as follows:

:host_variable INDICATOR :indicator_variable
A host language needs indicator variables because it cannot manipulate nulls. PL/SQL meets this need by allowing an embedded PL/SQL block to accept nulls from the host program and return nulls or truncated values to it.

In the following Pro*COBOL example, the PL/SQL block uses an indicator variable to return a null status code to the host program:

```sql
EXEC SQL EXECUTE
BEGIN
...
  WHERE EMPNO = :MY–EMPNO
END;
END–EXEC.

MOVE MY–COMM TO MY–COMM–OUT.
DISPLAY “Commission: ”
  WITH NO ADVANCING.
IF COMM–IND = –1
  * If the value returned by an indicator variable is –1,
  * its output host variable is null.
  DISPLAY “N/A”
ELSE
  DISPLAY MY–COMM–OUT.

Inside a PL/SQL block, an indicator variable must be prefixed with a colon and appended to its host variable.

You cannot refer to an indicator variable by itself. Furthermore, if you refer to a host variable with its indicator variable, you must always refer to it that way in the same block. In the next example, because the host variable appears with its indicator variable in the SELECT statement, it must also appear that way in the IF statement:

```sql
EXEC SQL EXECUTE
DECLARE
...
  status_unknown EXCEPTION;
BEGIN
...
  SELECT ename, job INTO :my_ename, :my_job:job_ind FROM emp
    WHERE empno = :my_empno;
  IF :my_job:job_ind IS NULL THEN
    RAISE status_unknown;
  END IF;
...
END;
END–EXEC;
```
Although you cannot refer directly to indicator variables inside a PL/SQL block, PL/SQL checks their values upon entering the block and sets their values correctly upon exiting the block.

**Nulls**

Upon entering a block, if an indicator variable has a value of –1, PL/SQL assigns a null to the host variable. Upon exiting the block, if a host variable is null, PL/SQL assigns a value of –1 to the indicator variable. In the following example, the exception *name_missing* is raised if the indicator variable *ename_ind* had a value of –1 before the PL/SQL block was entered:

```sql
EXEC SQL EXECUTE
DECLARE
   ... name_missing EXCEPTION;
BEGIN
   ...
   IF :my_ename:ename_ind IS NULL THEN
      RAISE name_missing;
   END IF;
   ...
EXCEPTION
   WHEN name_missing THEN
   ...
END;
END–EXEC;
```

**Truncated Values**

PL/SQL does not raise an exception when a truncated string value is assigned to a host variable. However, if you use an indicator variable, PL/SQL sets it to the original length of the string. In the following example, the host program will be able to tell, by checking the value of *ename_ind*, if a truncated value was assigned to *my_ename*:

```sql
EXEC SQL EXECUTE
DECLARE
   new_ename CHAR(10);
   ...
BEGIN
   ...
   :my_ename:ename_ind := new_ename;
   ...
END;
END–EXEC;
```
Using the VARCHAR Pseudotype

You can use the VARCHAR pseudotype to declare variable–length character strings. (A pseudotype is a datatype not native to your host language.) VARCHAR variables have a 2–byte length field followed by a string field of up to 65533 bytes. For example, the Pro*C Precompiler expands the declaration

```
EXEC SQL BEGIN DECLARE SECTION;
  VARCHAR my_ename[10]
EXEC SQL END DECLARE SECTION;
```

into the following DECLARE data structure:

```
struct {
  unsigned short len;
  unsigned char  arr[10];
} my_ename;
```

To get the length of a VARCHAR, simply refer to its length field. You need not use a string function or character–counting algorithm.

Oracle automatically sets the length field of a VARCHAR output host variable. However, to use a VARCHAR output host variable in your PL/SQL block, you must initialize the length field before entering the PL/SQL block. So, set the length field to the declared (maximum) length of the VARCHAR, as shown in the following Pro*C example:

```
EXEC SQL BEGIN DECLARE SECTION;
  int     my_empno;
  VARCHAR my_ename[10]   /* declare variable–length string */
  float   my_sal;
  ...
EXEC SQL END DECLARE SECTION;
...
my_ename.len = 10;   /* initialize length field */
EXEC SQL EXECUTE
BEGIN
  SELECT ename, sal INTO :my_ename, :my_sal FROM emp
  WHERE empno = :my_empno;
  ...
END;
END-EXEC;
```
If an embedded PL/SQL block refers to a database table that does not yet exist, the precompiler generates an error. To avoid such errors, you can use the DECLARE TABLE statement to tell the precompiler what the table will look like. In the following Pro*C example, you declare the `dept` table:

```
EXEC SQL DECLARE dept TABLE(
    deptno NUMBER(2),
    dname  VARCHAR2(14),
    loc    VARCHAR2(13));
```

If you use DECLARE TABLE to define a table that already exists, the precompiler uses your definition, ignoring the one in the Oracle data dictionary. Note that you cannot use the DECLARE TABLE statement inside a PL/SQL block.

The Oracle Precompilers can help you debug a program by checking the syntax and semantics of embedded SQL statements and PL/SQL blocks. You control the level of checking by entering the SQLCHECK option inline or on the command line. You can specify the following values for SQLCHECK:

- SEMANTICS
- SYNTAX
- NONE

However, if you embed PL/SQL blocks in your program, you must specify SQLCHECK=SEMANTICS. When SQLCHECK=SEMANTICS, the precompiler checks the syntax and semantics of SQL data manipulation statements and PL/SQL blocks.

The precompiler gets information needed for the semantic check by using embedded DECLARE TABLE statements or by connecting to Oracle and accessing the data dictionary. So, unless every database table referenced in a SQL statement or PL/SQL block is defined by a DECLARE TABLE statement, you must specify the option USERID on the command line. For more information see *Programmer’s Guide to the Oracle Precompilers*.

You can pass input host arrays and indicator arrays to a PL/SQL block. They can be indexed by a PL/SQL variable of type BINARY_INTEGER or by a host variable compatible with that type. Normally, the entire host array is passed to PL/SQL, but you can use the ARRAYLEN statement (discussed later) to specify a smaller array dimension.
Furthermore, you can use a procedure call to assign all the values in a host array to rows in a PL/SQL table. Given that the array subscript range is \( m .. n \), the corresponding PL/SQL table index range is always \( 1 .. n - m + 1 \). For example, if the array subscript range is \( 5 .. 10 \), the corresponding PL/SQL table index range is \( 1 .. (10 - 5 + 1) \) or \( 1 .. 6 \).

In the Pro*C example below, you pass a host array named `salary` to a PL/SQL block, which uses the host array in a function call. The function’s formal parameters include a PL/SQL table named `num_tab`. The function call assigns all the values in the actual parameter `salary` to rows in the formal parameter `num_tab`.

```c
#include <stdio.h>
main()
{
    /* Declare host array */
    EXEC SQL BEGIN DECLARE SECTION;
    ... 
    float  salary [100];
    EXEC SQL END DECLARE SECTION;
    /* Populate host array */
    ... 
    EXEC SQL EXECUTE
    DECLARE 
        TYPE NumTabTyp IS TABLE OF REAL
        INDEX BY BINARY_INTEGER;
        mid_salary  REAL;
        n  BINARY_INTEGER := 100;
        FUNCTION median (num_tab NumTabTyp, n INTEGER)
            RETURN REAL IS 
        BEGIN
            -- compute median
        END;
        BEGIN
        mid_salary := median(:salary, n);  -- pass array 
    ... 
    END;
    END-EXEC;
    ... 
}
```

You can also use a procedure call to assign all row values in a PL/SQL table to corresponding elements in a host array. (See Sample Program 6 in Appendix B.)
Table 8–1 shows the legal conversions between row values in a PL/SQL table and elements in a host array. For example, a host array of type LONG is compatible with a PL/SQL table of type LONG, LONG RAW, RAW, or VARCHAR2. Notably, it is not compatible with a PL/SQL table of type CHAR.

<table>
<thead>
<tr>
<th>PL/SQL Table</th>
<th>CHAR</th>
<th>DATE</th>
<th>LONG</th>
<th>LONG RAW</th>
<th>NUMBER</th>
<th>RAW</th>
<th>ROWID</th>
<th>VARCHAR2</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR</td>
<td>✓</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DATE</td>
<td></td>
<td>✓</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>LONG</td>
<td></td>
<td></td>
<td>✓</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>LONG RAW</td>
<td></td>
<td></td>
<td></td>
<td>✓</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>NUMBER</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RAW</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>ROWID</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>✓</td>
</tr>
<tr>
<td>VARCHAR2</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 8–1 Legal Datatype Conversions

The Oracle Precompilers do not check your usage of host arrays. For instance, no index range–checking is done.

**ARRAYLEN Statement**

Suppose you must pass an input host array to a PL/SQL block for processing. By default, when binding such a host array, the Oracle Precompilers use its declared dimension. However, you might not want to process the entire array, in which case you can use the ARRAYLEN statement to specify a smaller dimension. ARRAYLEN associates the host array with a host variable, which stores the smaller dimension.

Let us repeat the last example, but use ARRAYLEN to override the default dimension of host array `salary`:

```c
#include <stdio.h>
main()
{
    /* Declare host array */
    EXEC SQL BEGIN DECLARE SECTION;
    ...
    float  salary [100];
    int    my_dim;
    EXEC SQL ARRAYLEN salary (my_dim);
    EXEC SQL END DECLARE SECTION;
    /* Populate host array */
    ...
    /* Set smaller host array dimension */
    my_dim = 25;
```
EXEC SQL EXECUTE
DECLARE
   TYPE NumTabTyp IS TABLE OF REAL
   INDEX BY BINARY_INTEGER;
mid_salary  REAL;
FUNCTION median (num_tab NumTabTyp, n INTEGER)
   RETURN REAL IS
BEGIN
   -- compute median
END;
BEGIN
   mid_salary := median(:salary, :my_dim);  -- pass array
   ...
END;
END-EXEC;
...
}

Only 25 array elements are passed to the PL/SQL block because ARRAYLEN downsizes the host array from 100 to 25 elements. As a result, when the PL/SQL block is sent to Oracle for execution, a much smaller host array is sent along. This saves time and, in a networked environment, reduces network traffic.

The following Pro*C example shows how values are assigned to host array elements and how individual array elements are referenced:

```
#include <stdio.h>
...
main()
{
   /* Declare host and indicator arrays */
   EXEC SQL BEGIN DECLARE SECTION;
       float  sal [100];
       float  comm [100];
       short  icomm [100];
       int    i = 50;
   EXEC SQL END DECLARE SECTION;
   EXEC SQL EXECUTE
DECLARE
   TYPE SalTabTyp IS TABLE OF emp.sal%TYPE
   INDEX BY BINARY_INTEGER;
   TYPE CommTabTyp IS TABLE OF emp.comm%TYPE
   INDEX BY BINARY_INTEGER;
   sal_tab   SalTabTyp;
   comm_tab  CommTabTyp;
   j         BINARY_INTEGER := 0;
   ...
```
BEGIN
    /* Load salaries and commissions into PL/SQL tables */
    FOR emprec IN (SELECT sal, comm FROM emp) LOOP
        j := j + 1;
        sal_tab(j) := emprec.sal;
        comm_tab(j) := emprec.comm;
    END LOOP;
    /* Process the PL/SQL tables */
    ...
    /* Assign row values to host arrays */
    WHILE :i > 0 LOOP
        :sal(:i) := sal_tab(:i);
        /* if comm is assigned a null, icomm is assigned -1 */
        :comm:icomm(:i) := comm_tab(:i);
        :i := :i - 1;
    END LOOP;
END;
END–EXEC;
...

Using Dynamic SQL

Unlike static SQL statements, dynamic SQL statements are not embedded in your source program. Instead, they are stored in character strings input to (or built by) the program at run time. For example, they might be entered interactively or read from a file.

The Oracle Precompilers treat a PL/SQL block like a single SQL statement. So, like a SQL statement, a PL/SQL block can be stored in a string host variable for processing by dynamic SQL commands.

However, recall from Chapter 2 that you cannot use single–line comments in a PL/SQL block that will be processed dynamically. Instead, use multi–line comments.

Following is a brief look at how PL/SQL is used with dynamic SQL Methods 1, 2, and 4. For more information, see Programmer’s Guide to the Oracle Precompilers.

With Method 1

If your PL/SQL block contains no host variables, you can use Method 1 to execute the PL/SQL string in the usual way. In the following Pro*C example, you prompt the user for a PL/SQL block, store it in a string host variable named user_block, then execute it:

main()
{
    printf("Enter a PL/SQL block: ");
    scanf("%s", user_block);
    EXEC SQL EXECUTE IMMEDIATE :user_block;
When you store a PL/SQL block in a string host variable, omit the keywords EXEC SQL EXECUTE, the keyword END–EXEC, and the statement terminator.

With Method 2

If your PL/SQL block contains a known number of input and output host variables, you can use dynamic SQL Method 2 to prepare and execute the PL/SQL string in the usual way. In the Pro*C example below, the PL/SQL block uses one host variable named *my_empno*. The program prompts the user for a PL/SQL block, stores it in a string host variable named *user_block*, then prepares and executes the block:

```c
main()
{
    printf("\nEnter a PL/SQL block: ");
    scanf("%s", user_block);
    EXEC SQL PREPARE my_block FROM :user_block;
    EXEC SQL EXECUTE my_block USING :my_empno;
}
```

Note that *my_block* is an identifier used by the precompiler, not a host or program variable.

The precompiler treats all PL/SQL host variables as input host variables whether they serve as input or output host variables (or both) inside the PL/SQL block. So, you must put all host variables in the USING clause.

When the PL/SQL string is executed, host variables in the USING clause replace corresponding placeholders in the prepared string. Although the precompiler treats all PL/SQL host variables as input host variables, values are assigned correctly. Input (program) values are assigned to input host variables, and output (column) values are assigned to output host variables.

With Method 4

If your PL/SQL block contains an unknown number of input or output host variables, you must use Method 4. To do so, you set up a bind descriptor for all the input and output host variables. Executing the DESCRIBE BIND VARIABLES statement stores information about input and output host variables in the bind descriptor.
Without dynamic SQL, you cannot use PL/SQL variables in a query to specify database columns. Consider the SELECT statement below, which does not assign a value from the ename database column to the variable my_ename. Instead, if the emp table has a column named colx, a value from that column is assigned to my_ename. If the table has no such column, the value of PL/SQL variable colx (that is, the string value 'ename') is assigned to my_ename.

```plsql
DECLARE
  colx     VARCHAR2(10);
  my_ename VARCHAR2(10);
...
BEGIN
  colx := 'ename';
  SELECT colx INTO my_ename FROM emp WHERE ...
  ...
END;
```

However, you can mimic dynamic SQL by using the DECODE function. In the following example, the data returned depends on the value of my_column:

```plsql
DECLARE
  my_column VARCHAR2(10);
  my_data   emp.ename%TYPE;
BEGIN
 ...
  my_column := 'hiredate';
  ...
  SELECT DECODE(my_column, 'ename', ename,
                'hiredate', TO_CHAR(hiredate, 'ddmmyy'), 'empno', empno)
       INTO my_data FROM emp WHERE ... ;
END;
```

The value that DECODE returns is always forced to the datatype of the first result expression. In this example, the first result expression is ename, which has datatype VARCHAR2, so the returned value is forced to type VARCHAR2. Thus, my_data is correctly declared as emp.ename%TYPE.

You can use this technique in many environments. For example, it works in SQL*Plus and Oracle Forms.
To call a stored subprogram from a host program, you must use an anonymous PL/SQL block. In the following example, you call the standalone procedure `create_dept`:

```sql
EXEC SQL EXECUTE
BEGIN
    create_dept(:number, :name, :location);
END;
END-EXEC;
```

Notice that the actual parameters `number`, `name`, and `location` are host variables.

In the next example, the procedure `create_dept` is part of a package named `emp_actions`, so you must use dot notation to qualify the procedure call:

```sql
EXEC SQL EXECUTE
BEGIN
    emp_actions.create_dept(:number, :name, :location);
END;
END-EXEC;
```

The OCIs process SQL statements and PL/SQL blocks similarly with one exception. Inside a PL/SQL block, you must use the OBNDR or OBNDRV call, not ODEFIN, to bind all placeholders in a SQL or PL/SQL statement. This holds for both input and output placeholders. The ODEFIN call is not supported for PL/SQL blocks.

In PL/SQL, all queries must have an INTO clause containing placeholders (host variables and/or PL/SQL variables) that correspond to items in the select list. For example, the following SELECT statement is not valid inside a PL/SQL block:

```sql
SELECT ename, sal FROM emp;
```

Instead, it must be coded as follows:

```sql
SELECT ename, sal INTO :my_ename, :my_sal FROM emp;
```

In the last statement, `my_ename` and `my_sal` are SQL placeholders that correspond to the `ename` and `sal` columns in the select list. You must bind these placeholders using the OBNDR or OBNDRV call. Use the OBNDR call to bind host arrays to PL/SQL tables.
Also, you must use named placeholders such as `my_ename` in PL/SQL blocks. Numbered placeholders such as `10` and the corresponding `OBNDRN` call are not supported for PL/SQL blocks.

A Complete Example

The OCI program below, which is written in C, shows how two PL/SQL banking transactions might be implemented. You can find listings of the header files `ocidfn.h` and `ocidem.h`, in *Programmer's Guide to the Oracle Call Interface*.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#define ANSI
#include "ocidfn.h"
#include "ocidem.h"
cda_def cda;
lda_def lda;
char hda[256];

void
error_handler(struct cda_def *cda)
{
    char  msg[512];
    int   n;
    printf("\n>>> Oracle Error\n");
    n = oerhms(&lda, cda->rc, msg, sizeof(msg));
    printf("%.%s\n", n, msg);
    printf("Processing OCI function %s\n",
           oci_func_tab[cda->fc]);
}

Calling Stored Subprograms

To call a stored subprogram from an OCI program, you must use an anonymous PL/SQL block. In the following C example, a call to the standalone procedure raise_salary is copied into the string variable plsql_block:

strcpy(plsql_block, "BEGIN raise_salary(:emp_id, :amount); END;");

Then, the PL/SQL string can be bound and executed like a SQL statement.
Language Reference
Chapter 9

Language Elements

Grammar, which knows how to control even kings.

Molière

This chapter uses syntax diagrams to show you how commands, parameters, and other language elements are sequenced to form PL/SQL statements. It serves as a quick reference guide to PL/SQL syntax and coding conventions. Also, it provides usage notes and short examples to save you time and trouble.
The following sections are arranged alphabetically for easy reference:

Assignment Statement %NOTFOUND Attribute
Blocks NULL Statement
CLOSE Statement OPEN Statement
Comments OPEN–FOR Statement
COMMIT Statement Packages
Conditions PL/SQL Tables
Cursors Procedures
Cursor Variables RAISE Statement
DELETE Statement Records
EXCEPTION_INIT Pragma RETURN Statement
Exceptions ROLLBACK Statement
EXIT Statement %ROWCOUNT Attribute
Expressions %ROWTYPE Attribute
FETCH Statement SAVEPOINT Statement
%FOUND Attribute SELECT INTO Statement
Functions SET TRANSACTION Statement
GOTO Statement SQL Cursor
IF Statement SQLCODE Function
INSERT Statement SQLERRM Function
%ISOPEN Attribute %TYPE Attribute
Literals UPDATE Statement
LOCK TABLE Statement Variables and Constants
LOOP Statement

Each of these sections has some or all of the following subsections:

Description
Syntax
Keyword and Parameter Description
Usage Notes
Examples
Related Topics

Easy-to-understand syntax diagrams are used to illustrate PL/SQL syntax. If you are not familiar with syntax diagrams, do not worry. The next section tells you all you need to know.
Using Syntax Diagrams

If you are unsure of the exact syntax to use in a PL/SQL statement, refer to its syntax diagram. A syntax diagram is a line–and–arrow drawing that depicts valid syntax. You can verify or construct any PL/SQL statement by tracing through its syntax diagram.

How to Read Syntax Diagrams

Syntax diagrams use lines and arrows to show how commands, parameters, and other language elements are sequenced to form statements. Follow each diagram in the direction shown by the lines and arrows. The following symbols will guide you:

- Marks the beginning of the diagram.
- Marks the end of the diagram.
- Shows that the diagram continues on a line below.
- Shows that the diagram is continued from a line above.
- Represents a loop.

If the syntax diagram contains more than one possible path, you must select the path appropriate for your program.

If you have the choice of more than one keyword, operator, or parameter, the choices appear in a vertical list. In the following examples, you can travel up or down a vertical line as far as you like, then continue along any horizontal line:
Required Parameters

Required parameters can appear singly or in a vertical list of alternatives. Single required parameters appear on the main path, that is, on the horizontal line you are currently traveling. In the following example, `label_name` is a required parameter:

```
GOTO label_name;
```

If there is a label named `update_row`, then, according to the diagram, the following statement is valid:

```
GOTO update_row;
```

If any of the parameters in a vertical list appears on the main path, one of them is required. That is, you must choose one of the parameters but not necessarily the one that appears on the main path. In the following example, you must choose one of the four types of expressions:

```
num_expression
  | char_expression
  | date_expression
  | boolean_expression
```

Optional Parameters

If parameters appear in a vertical list below the main path, they are optional; that is, you need not choose any of them. In the following example, instead of traveling down the vertical line, you can continue along the main path:

```
COMMIT WORK COMMENT 'text';
```

According to the diagram, all of the following statements are valid:

```
COMMIT;
COMMIT WORK;
COMMIT COMMENT 'In-doubt transaction; notify Order Entry';
COMMIT WORK COMMENT 'In-doubt transaction; notify Order Entry';
```
Syntax Loops

Loops let you repeat the syntax contained within them as many times as you like. In the following example, each list of declarations is inside a loop. So, after choosing one type of declaration, you can go back repeatedly to choose the same or another type.

```
DECLARE
  procedure_declaration
  function_declaration
  variable_declaration
  constant_declaration
  cursor_declaration
  cursor_variable_declaration
  exception_declaration
  record_declaration
  plsql_table_declaration
  DECLARE
  procedure_declaration
  functionDeclaration
```

According to the diagram, all of the following declarations are valid:

First example:
```
DECLARE
  credit_limit CONSTANT NUMBER(7,2) := 5000.00;
```

Second example:
```
DECLARE
  over_limit EXCEPTION;
  past_due EXCEPTION;
```

Third example:
```
DECLARE
  account_name VARCHAR2(25);
  over_limit EXCEPTION;
  new_balance NUMBER(9,2);
  old_balance NUMBER(9,2);
  past_due EXCEPTION;
  PROCEDURE raise_salary (emp_id INTEGER, amount REAL) IS
  BEGIN ... END;
```

The following subprogram declaration is illegal because it precedes the variable declaration:
```
DECLARE
  PROCEDURE raise_salary (emp_id INTEGER, amount REAL) IS
  BEGIN ... END; -- illegal; must come last
  old_salary NUMBER(7,2);
```
Multi-part Syntax Diagrams

Read a multi–part diagram as if all the main paths were joined end to end. The following example is a two–part diagram:

```
INSERT INTO table_reference (column_name)
VALUES (sql_expression)
```

If there is a table named salaries with columns named grade, low, middle, and high, then, according to the diagram, the following statement is valid:

```
INSERT INTO salaries (grade, low, high) VALUES (4, 2000, 2999);
```

How to Code from a Syntax Diagram

To code from a syntax diagram, go to the beginning mark, then follow the lines and arrows. When you meet a keyword, spell it exactly as shown. Case does not matter. When you meet a parameter, replace it with the value, identifier, or object it represents. (If the parameter has its own syntax diagram, detour to that diagram, then return.) When you meet operators, delimiters, or terminators, type them exactly as shown. You must separate keywords and identifiers with spaces.

In the following example, first you meet a keyword, then a parameter, and finally a terminator:

```
GOTO label_name;
```

If there is a label named end_loop, then, according to the diagram, you code the statement as follows:

```
GOTO end_loop;
```

Be sure to read the parameter descriptions and usage notes. If you use certain keywords, clauses that are normally optional might be required. For example, if you use the keyword CONSTANT in a variable declaration, you must include an initialization clause.
Assignment Statement

Description  
An assignment statement sets the current value of a variable, formal parameter, field in a record, or row in a PL/SQL table. For more information, see “Assignments” on page 2 – 27.

Syntax  
assignment statement ::=

object_name := plsql_expression ;

object ::= 

-- plsql_variable
  -- record.field
  -- plsql_table(subscript)
  -- :host_variable
  -- cursor_variable

Alternatively, you can use the SELECT or FETCH statement to have Oracle assign values to a variable.

Keyword and Parameter Description

object_name  
This is the name of a previously declared object to which you want to assign a value.

plsql_expression  
This is an arbitrarily complex expression. The syntax of plsql_expression is defined in “Expressions” on page 9 – 40. The value of plsql_expression is assigned to the object identified by object_name. The datatype of plsql_expression must be compatible with the datatype of object. For more information, see “Datatype Conversion” on page 2 – 16.

plsql_variable  
This is a PL/SQL variable previously declared within the current scope.

record.field  
This is a field in a user-defined or %ROWTYPE record previously declared within the current scope.

plsql_table(subscript)  
This is a row in a PL/SQL table previously declared within the current scope.

host_variable  
This is a host variable previously declared within the current scope. For information about host objects, see “Host Objects” on page 9 – 43.

cursor_variable  
This is a previously declared cursor variable.
Usage Notes

By default, unless an object is initialized in its declaration, it is initialized to NULL every time a block or subprogram is entered. So, never reference an object before you assign it a value.

You cannot assign nulls to a variable defined as NOT NULL. If you try, PL/SQL raises the predefined exception VALUE_ERROR.

Only the values TRUE and FALSE and the non-value NULL can be assigned to a Boolean variable. When applied to PL/SQL expressions, the relational operators return a Boolean value. So, the following assignment is legal:

```plsql
DECLARE
    out_of_range BOOLEAN;
BEGIN
    ...
    out_of_range := (salary < minimum) OR (salary > maximum);
END;
```

As the next example shows, you can assign the value of a PL/SQL expression to a specific field in a record:

```plsql
DECLARE
    emp_rec emp%ROWTYPE;
BEGIN
    ...
    emp_rec.sal := current_salary + increase;
END;
```

Moreover, you can assign values to all fields in a record at once. PL/SQL allows aggregate assignment between entire records if their declarations refer to the same cursor or table. For example, the following assignment is legal:

```plsql
DECLARE
    emp_rec1 emp%ROWTYPE;
    emp_rec2 emp%ROWTYPE;
    dept_rec dept%ROWTYPE;
BEGIN
    ...
    emp_rec1 := emp_rec2;
END;
```

The next assignment is illegal because you cannot use the assignment operator to assign a list of values to a record:

```plsql
depth_rec := (60, 'PUBLICITY', 'LOS ANGELES');
```

You can assign the value of a PL/SQL expression to a specific row in a PL/SQL table by using the syntax

```plsql
plsql_table_name(primary_key_value) := plsql_expression;
```
In the following example, you assign the uppercase value of `last_name` to the third row in PL/SQL table `ename_tab`:

```plsql
ename_tab(3) := UPPER(last_name);
```

**Examples**

```plsql
wages := hours_worked * hourly_salary;
country := 'France';
costs := labor + supplies;
done := (count > 100);
department_rec.loc := 'BOSTON';
comm_tab(5) := sales * 0.15;
```

**Related Topics**

Expressions, FETCH, SELECT INTO, Variables and Constants
Blocks

Description

The basic program unit in PL/SQL is the block. A PL/SQL block is defined by the following reserved words: DECLARE, BEGIN, EXCEPTION, and END. These keywords partition the PL/SQL block into a declarative part, an executable part, and an exception-handling part. Only the executable part is required.

You can nest a block within another block wherever you can place an executable statement. For more information, see “Block Structure” on page 1–3 and “Scope and Visibility” on page 2–25.

Syntax

```
plsql_block ::= 
<<label_name>>
BEGIN
  seq_of_statements
END
exception_handler
EXCEPTION
label_name;
```
Keyword and Parameter Description

label_name

This is an undeclared identifier that optionally labels a PL/SQL block. For naming conventions, see “Identifiers” on page 2–4. If used, label_name must be enclosed by double angle brackets and must appear at the beginning of the block. (However, in the SQL*Plus environment, the first line you input cannot start with a label.) Optionally, label_name can also appear at the end of the block.

A global identifier declared in an enclosing block can be redeclared in a sub–block, in which case the local declaration prevails and the sub–block cannot reference the global identifier. To reference the global identifier, you must use a block label to qualify the reference, as follows:

block_label.global_identifier

In the following example, you compare two INTEGER variables declared with the same name, one in an enclosing block, the other in a sub–block:

<<outer>>
DECLARE
  x INTEGER;
BEGIN
  ...
  DECLARE
    x INTEGER;
  BEGIN
    ...
    IF x = outer.x THEN
      ...
      END IF;
    END;
  END outer;

DECLARE

This keyword signals the start of the declarative part of a PL/SQL block, which contains local declarations. Objects declared locally exist only within the current block and all its sub–blocks and are not visible to enclosing blocks.

The declarative part of a PL/SQL block is optional. It is terminated implicitly by the keyword BEGIN, which introduces the executable part of the block.

PL/SQL does not allow forward references. So, you must declare an object before referencing it in other statements, including other declarative statements.
You must declare subprograms at the end of a declarative section after all other program objects. For example, the following procedure declaration is misplaced:

```
DECLARE
    PROCEDURE award_bonus (...) IS -- misplaced; must come last
    BEGIN ... END;
    rating NUMBER;

    You can use the pragma EXCEPTION_INIT in the declarative part of a block to associate exception names with Oracle error numbers. For more information, see “Using EXCEPTION_INIT” on page 5 – 9.
```

**variable_declaration**
This construct declares a variable. For the syntax of `variable_declaration`, see “Variables and Constants” on page 9 – 120.

**constant_declaration**
This construct declares a constant. For the syntax of `constant_declaration`, see “Variables and Constants” on page 9 – 120.

**cursor_declaration**
This construct declares an explicit cursor. For the syntax of `cursor_declaration`, see “Cursors” on page 9 – 23.

**cursor_variable_declaration**
This construct declares a cursor variable. For the syntax of `cursor_variable_declaration`, see “Cursor Variables” on page 9 – 27.

**exception_declaration**
This construct declares an exception. For the syntax of `exception_declaration`, see “Exceptions” on page 9 – 35.

**record_declaration**
This construct declares a user-defined record. For the syntax of `record_declaration`, see “Records” on page 9 – 94.

**plsql_table_declaration**
This construct declares a PL/SQL table. For the syntax of `plsql_table_declaration`, see “PL/SQL Tables” on page 2 – 38.

**procedure_declaration**
This construct declares a procedure. For the syntax of `procedure_declaration`, see “Procedures” on page 9 – 88.

**function_declaration**
This construct declares a function. For the syntax of `function_declaration`, see “Functions” on page 9 – 50.
BEGIN
This keyword signals the start of the executable part of a PL/SQL block, which contains executable statements. The executable part of a PL/SQL block or subprogram is required. That is, a block or subprogram must contain at least one executable statement. The NULL statement meets this requirement, as the following example shows:

```
BEGIN
    NULL;
END;
```

seq_of_statements
This represents a sequence of statements. The syntax is

```
seq_of_statements ::=...
```

where `statement` can be any legal PL/SQL statement, including another `plsql_block`. Variable, constant, and exception declarations are declarative (not executable) statements.

statement
This construct is used to create algorithms. There are PL/SQL `statements` for conditional, iterative, and sequential control, as well as for error handling. PL/SQL `statements` are free format; that is, they can continue from line to line, providing you do not split keywords, delimiters, or literals across lines. A semicolon (;) must terminate every PL/SQL `statement`. The syntax of `statement` follows:

```
statement ::= ...
```

Language Elements
sql_statement

Following is the syntax of sql_statement, which is defined in PL/SQL as a specific subset of all SQL statements and excludes data definition and data control statements:

```
```

EXCEPTION

This keyword signals the start of the exception–handling part of a PL/SQL block. When an exception is raised, normal execution of the block stops and control transfers to the appropriate exception handler. After the exception handler completes, execution proceeds with the statement following the block.

If there is no exception handler for the raised exception in the current block, control passes to the enclosing block. This process repeats until an exception handler is found or there are no more enclosing blocks. If PL/SQL can find no exception handler for the exception, execution of the block stops and an unhandled exception error is returned to the host environment. For more information, see Chapter 5.

exception_handler

This construct associates an exception with a sequence of statements, which is executed when that exception is raised. For the syntax of exception_handler, see “Exceptions” on page 9–35. A couple of examples follow:

```
EXCEPTION
  WHEN ZERO_DIVIDE THEN  -- division by zero exception
    ROLLBACK;
  WHEN VALUE_ERROR THEN  -- constraint violation
    INSERT INTO audit_table
      VALUES (trans_id, kind, amount, 'Overflow Error');
    COMMIT;
  ...
END;
```
This keyword signals the end of a PL/SQL block. It must be the last keyword in a block. Neither the END IF in an IF statement nor the END LOOP in a LOOP statement can substitute for the keyword END.

Example

```
-- available online in file EXAMP11
DECLARE
  numerator   NUMBER;
  denominator NUMBER;
  the_ratio   NUMBER;
  lower_limit CONSTANT NUMBER := 0.72;
  samp_num    CONSTANT NUMBER := 132;
BEGIN
  SELECT x, y INTO numerator, denominator FROM result_table
    WHERE sample_id = samp_num;
  the_ratio := numerator/denominator;
  IF the_ratio > lower_limit THEN
    INSERT INTO ratio VALUES (samp_num, the_ratio);
  ELSE
    INSERT INTO ratio VALUES (samp_num, -1);
  END IF;
  COMMIT;
EXCEPTION
  WHEN ZERO_DIVIDE THEN
    INSERT INTO ratio VALUES (samp_num, 0);
    COMMIT;
  WHEN OTHERS THEN
    ROLLBACK;
END;
```

CLOSE Statement

Description
The CLOSE statement allows resources held by an open cursor or cursor variable to be reused. No more rows can be fetched from a closed cursor or cursor variable. For more information, see “Processing Transactions” on page 4 – 35.

Syntax

```sql
close_statement ::= 
CLOSE
cursor_name
:cursor_variable_name
```

Keyword and Parameter Description

cursor_name
This is the name of a previously declared and currently open cursor.

cursor_variable_name
This is the name of a cursor variable declared in a PL/SQL host environment and passed to PL/SQL as a bind variable. The datatype of the host cursor variable is compatible with the return type of any PL/SQL cursor variable. In SQL statements, host variables must be prefixed with a colon. For more information, see “Host Objects” on page 9 – 43.

Usage Notes
Once a cursor is closed, you can reopen it either by using the OPEN statement to re-evaluate parameters and reinitialize the active set, or by using a cursor FOR loop to open the cursor implicitly.

PL/SQL raises the predefined exception INVALID_CURSOR if you try to close an already–closed or never–opened cursor or cursor variable.

Cursor variables must be opened on the server side, but you can close them on the client side or server side. You need not close a cursor variable before reopening it.

Example
In the following Pro*C example, when the last row is processed, you close the cursor variable `emp_cur`:

```c
for (;;) {
    EXEC SQL FETCH :emp_cur INTO :emp_rec;
    /* process the data. */
}
/* Close cursor variable. */
EXEC SQL CLOSE :emp_cur;
```

Related Topics
DECLARE, FETCH, OPEN, OPEN–FOR
Comments

Description
Comments describe the purpose and use of code segments and so promote readability. PL/SQL supports two comment styles: single-line and multi-line. Single-line comments begin with a double hyphen (– –) anywhere on a line and extend to the end of the line. Multi-line comments begin with a slash-asterisk (/*), end with an asterisk-slash (*/), and can span multiple lines. For more information, see “Comments” on page 2–8.

Syntax

:\n
| comment ::= \n| | text \n| \n| text \n
Usage Notes
Comments can appear within a statement at the end of a line. However, you cannot nest comments. Also, you cannot use single-line comments in a PL/SQL block that will be processed dynamically by an Oracle Precompiler program because end-of-line characters are ignored. As a result, single-line comments extend to the end of the block, not just to the end of a line. Instead, use multi-line comments.

While testing or debugging a program, you might want to disable a line of code. The following example shows how you can “comment-out” the line:

\n
-- UPDATE dept SET loc = my_loc WHERE deptno = my_deptno;
\n
You can use multi-line comment delimiters to comment-out whole sections of code.

Examples

-- compute the area of a circle
area := pi * radius**2; -- pi equals 3.14159

/* compute the area
of a circle */
area := pi * radius**2; /* pi equals 3.14159 */
The COMMIT statement explicitly makes permanent any changes made to the database during the current transaction. Changes made to the database are not considered permanent until they are committed. A commit also makes the changes visible to other users. For more information, see “Processing Transactions” on page 4–35.

Syntax

```
commit_statement ::= 
  COMMIT [ WORK ] [ COMMENT 'text' ] ;
```

Keyword and Parameter Description

WORK

This keyword is optional and has no effect except to improve readability.

COMMENT

This keyword specifies a comment to be associated with the current transaction and is typically used with distributed transactions. The text must be a quoted literal up to 50 characters long.

Usage Notes

The COMMIT statement releases all row and table locks. It also erases any savepoints you marked since the last commit or rollback. Until your changes are committed, the following conditions hold:

- You can see the changes when you query the tables you modified, but other users cannot see the changes.
- If you change your mind or need to correct a mistake, you can use the ROLLBACK statement to roll back (undo) the changes.

If you commit while a cursor that was declared using FOR UPDATE is open, a subsequent fetch on that cursor raises an exception. The cursor remains open, however, so you should close it. For more information, see “Using FOR UPDATE” on page 4–41.

When a distributed transaction fails, the text specified by COMMENT helps you diagnose the problem. If a distributed transaction is ever in doubt, Oracle stores the text in the data dictionary along with the transaction ID. For more information about distributed transactions, see Oracle7 Server Concepts.
With embedded SQL, the optional RELEASE parameter is allowed after COMMIT WORK. Serving the purpose of a “disconnect” statement, RELEASE signifies that you want to log off the database once your transaction is committed. Since PL/SQL does not allow data control statements such as CONNECT, GRANT, and REVOKE, it does not allow the RELEASE parameter.

Related Topics

ROLLBACK, SAVEPOINT
Conditions

Description

PL/SQL conditions are the basis for conditional control. They are allowed wherever a Boolean expression is allowed. Like a Boolean expression, a PL/SQL condition always yields TRUE, FALSE, or NULL.

In conditional control statements, if a PL/SQL condition yields TRUE, its associated sequence of statements is executed. If a PL/SQL condition yields FALSE or NULL, its associated sequence of statements is not executed. For more information, see “Expressions and Comparisons” on page 2–28.

Syntax

\[
\text{plsql\_condition} ::= \text{boolean\_expression} \\
\text{boolean\_expression} ::= \\
\text{AND} \quad \text{OR} \quad \text{NOT} \quad \text{boolean\_literal} \quad \text{boolean\_variable} \quad \text{boolean\_function\_call} \quad \text{other\_boolean\_forms} \\
\text{other\_boolean\_forms} ::= \\

\]
Keyword and Parameter Description

**AND, OR, NOT**
These logical operators follow the tri-state logic of the truth tables on page 2–30. AND returns the value TRUE only if both its operands are true. OR returns the value TRUE if either of its operands is true. NOT returns the opposite value (logical negation) of its operand. NOT NULL returns NULL because nulls are indeterminate. For more information, see “Logical Operators” on page 2–30.

**boolean_literal**
This is the predefined value TRUE or FALSE or the non-value NULL, which stands for a missing, unknown, or inapplicable value. You cannot insert the values TRUE and FALSE into a database column.

**boolean_variable**
This is any variable or constant that has datatype BOOLEAN. Only the values TRUE and FALSE and the non-value NULL can be assigned to a BOOLEAN variable. You cannot select or fetch column values into a BOOLEAN variable. Also, arithmetic operations on Boolean variables are illegal.

**boolean_function_call**
This is any function call that returns a value of type BOOLEAN.

**boolean_expression**
When parentheses enclose a boolean_expression that is part of a larger boolean_expression, PL/SQL evaluates the innermost expression first. The result value is then used in the larger expression.

**plsql_expression**
This is an arbitrarily complex expression. The syntax of plsql_expression is defined in “Expressions” on page 9–40.

**relational_operator**
This operator allows you to compare arbitrarily complex expressions. For the meaning of each operator, see “Comparison Operators” on page 2–31.

**IS [NOT] NULL**
This comparison operator returns the Boolean value TRUE if its operand is null, or FALSE if it is not null.

**[NOT] LIKE**
This comparison operator compares a character value to a pattern. Case is significant. LIKE returns the Boolean value TRUE if the character patterns match, or FALSE if they do not match.

**pattern**
This is a character string compared by the LIKE operator to a specified string value. It can include two special-purpose characters called wildcards. An underscore (_) matches exactly one character; a percent sign (%) matches zero or more characters.
This comparison operator tests whether a value lies in a specified range. It means “greater than or equal to low value and less than or equal to high value.”

This comparison operator tests set membership. It means “equal to any member of.” The set can contain nulls, but they are ignored. Also, expressions of the form

value NOT IN set

cursor_name

This is the name of a previously declared cursor.

cursor_variable_name

This is the name of a previously declared cursor variable.

When appended to the name of a cursor or cursor variable, these attributes let you access useful information about the execution of a multi-row query. You can also append them to the implicit SQL cursor, in which case their values always refer to the most recently executed SQL statement. For more information, see “Managing Cursors” on page 4 – 10.

In a plsql_condition, you can only compare values that have compatible datatypes. For more information, see “Datatype Conversion” on page 2 – 16.

When PL/SQL evaluates a boolean_expression, NOT has the highest precedence, AND has the next-highest precedence, and OR has the lowest precedence. However, you can use parentheses to override the default operator precedence.

The relational operators can be applied to operands of type BOOLEAN. By definition, TRUE is greater than FALSE. Comparisons involving nulls always yield a null.

The value of a Boolean expression can be assigned only to Boolean variables, not to host variables or database columns. Furthermore, no implicit or explicit datatype conversion to (or from) type BOOLEAN is supported.

Assignment Statement, EXIT, Expressions, IF, LOOP

Assignment Statement, EXIT, Expressions, IF, LOOP
Cursors

Description

For queries that return more than one row, a cursor lets you name the query and process the rows individually. For more information, see “Managing Cursors” on page 4 – 10.

Syntax

```plaintext
cursor_declaration ::=  
  CURSOR cursor_name  
  ( parameter )  
  IS  
  select_statement  
  ;

cursor_specification ::=  
  CURSOR cursor_name  
  ( parameter )  
  RETURN  
  record_type  
  record_variable%TYPE  
  cursor%ROWTYPE  
  table%ROWTYPE  
  ;

cursor_body ::=  
  CURSOR cursor_name  
  ( parameter )  
  RETURN  
  record_type  
  record_variable%TYPE  
  cursor%ROWTYPE  
  table%ROWTYPE  
  IS  
  select_statement  
  ;
```
## Keyword and Parameter Description

| cursor_name | This is the name of a cursor. The cursor name is like a function name and follows the usual scope rules. For naming conventions, see “Identifiers” on page 2 – 4. |
| parameter_name | This is the name of a cursor formal parameter. A cursor parameter can appear in a query wherever a constant can appear. The formal parameters of a cursor must be IN parameters. For information about parameter modes, see “Parameter Modes” on page 6 – 13. The query can also reference other PL/SQL variables within its scope. |
| parameter_type | This specifies the datatype of a cursor parameter. The datatype of the corresponding actual parameter must be compatible with parameter_type. For more information, see “Datatype Conversion” on page 2 – 16. |
| RETURN | This keyword introduces the RETURN clause, which defines the datatype of a cursor result value. You can use the %ROWTYPE attribute in a RETURN clause to provide a record that represents a row in a database table. You can also use the %TYPE attribute in a RETURN clause to provide the datatype of a record variable. A cursor body must have a SELECT statement and the same RETURN clause as its corresponding cursor specification. Furthermore, the number, order, and datatypes of select–items in the SELECT statement must match the RETURN clause. |

where parameter stands for the following syntax:

```
<table>
<thead>
<tr>
<th>parameter_name</th>
<th>IN</th>
<th>datatype_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>variable%TYPE</td>
<td>variable%TYPE</td>
<td></td>
</tr>
<tr>
<td>record_variable%TYPE</td>
<td>record_variable%TYPE</td>
<td></td>
</tr>
<tr>
<td>plsql_table%TYPE</td>
<td>plsql_table%TYPE</td>
<td></td>
</tr>
<tr>
<td>table.column%TYPE</td>
<td>table.column%TYPE</td>
<td></td>
</tr>
<tr>
<td>table%ROWTYPE</td>
<td>table%ROWTYPE</td>
<td></td>
</tr>
<tr>
<td>cursor%ROWTYPE</td>
<td>cursor%ROWTYPE</td>
<td></td>
</tr>
<tr>
<td>cursor_variable%ROWTYPE</td>
<td>cursor_variable%ROWTYPE</td>
<td></td>
</tr>
</tbody>
</table>
```

```
single_expression :=
plsql_expression
```

**DEFAULT**
This specifies the datatype of the result value returned by the cursor. For more information, see “Datatypes” on page 2 – 9.

table
This refers to a database table that must be accessible when the declaration is elaborated. (The processing of a declaration by the PL/SQL compiler is called elaboration.)

%TYPE
This attribute provides the datatype of a variable or database column.

%ROWTYPE
This attribute provides a record that represents a row in a database table. Columns in the row and corresponding fields in the record have the same names and datatypes.

select_statement
This is a query associated with cursor_name, which returns a set of values. The syntax of select_statement is like the syntax of select_into_statement (see “SELECT INTO Statement” on page 9 – 107), except that select_statement cannot have an INTO clause.

If the cursor declaration declares parameters, each parameter must be used in the select_statement.

Usage Notes
You must declare a cursor before referencing it in an OPEN, FETCH, or CLOSE statement. And, you must declare a variable before referencing it in a cursor declaration.

You cannot assign values to a cursor name or use it in an expression. However, cursors and variables follow the same scoping rules. For more information, see “Scope and Visibility” on page 2 – 25.

The word SQL is reserved by PL/SQL for use as the default name for implicit cursors and cannot be used in a cursor declaration.

You retrieve data from a cursor by opening it, then fetching from it. Since the FETCH statement specifies the target variables, using an INTO clause in the SELECT statement of a cursor_declaration is redundant and invalid.

The scope of cursor parameters is local to the cursor, meaning that they can be referenced only within the query used in the cursor declaration. The values of cursor parameters are used by the associated query when the cursor is opened. The query can also reference other PL/SQL variables within its scope. The parameter_type cannot be constrained. For example, you must specify NUMBER, not NUMBER(11,2).
Examples

Some examples of cursor declarations follow:

```sql
CURSOR c1 IS
    SELECT ename, job, sal FROM emp WHERE deptno = 20;

CURSOR c2 (start_date DATE) IS
    SELECT empno, sal FROM emp WHERE hiredate > start_date;
```

Cursor Variables

Description
Cursor variables are like C or Pascal pointers, which hold the memory location (address) of some object instead of the object itself. To execute a multi-row query, Oracle opens an unnamed work area that stores processing information. To access the information, you can use an explicit cursor, which names the work area. Or, you can use a cursor variable, which points to the work area. For more information, see “Using Cursor Variables” on page 4–17.

You must declare and initialize a cursor variable in a PL/SQL host environment such as a Pro*C or OCI program. To use the host cursor variable, you must pass it as a bind variable to PL/SQL, open it on the server side, then fetch from it back on the client side.

This section focuses on PL/SQL cursor variables. For more information about host cursor variables, see your Oracle tool user’s guide.

Syntax

cursor_variable_declaration ::= ref_cursor_type + cursor_variable

ref_cursor_type ::= 

 TYPE type_name IS REF CURSOR ;

RETURN record_variable%TYPE |

record_type |

table%ROWTYPE |

cursor%ROWTYPE |

cursor_variable%ROWTYPE

cursor_variable ::= 

cursor_variable_name type_name ;
This keyword introduces the RETURN clause, which specifies the datatype of a cursor variable result value. You can use the %ROWTYPE attribute in the RETURN clause to provide a record type that represents a row in a database table or a row returned by a (previously declared) cursor or cursor variable. You can also use the %TYPE attribute in the RETURN clause to provide the datatype of a record variable.

This identifier names a PL/SQL cursor variable. The cursor variable name follows the usual scoping rules. For naming conventions, see “Identifiers” on page 2 – 4.

You must declare a cursor variable in two steps. First, you define a REF CURSOR type, then declare a cursor variable of that type. You can define REF CURSOR types in any PL/SQL block, subprogram, or package. However, you can declare cursor variables only in a block or subprogram. Currently, REF CURSOR is the only reference (pointer) type that you can define.

Once you define a REF CURSOR type, you can declare cursor variables of that type. They follow the usual scoping and instantiation rules. You cannot assign one cursor variable to another unless they have the same datatype.

You can define subprograms that declare PL/SQL cursor variables as formal parameters and/or local variables. However, you cannot execute such subprograms unless each PL/SQL cursor variable points to a cursor work area designated by some host cursor variable.

You can make a PL/SQL cursor variable point to a valid cursor work area in the following ways:

- Assign a host cursor variable to a local PL/SQL cursor variable.
- Pass a host cursor variable to a subprogram that declares a cursor variable as its formal parameter.
- Assign or pass a PL/SQL cursor variable that already points to a cursor work area to another cursor variable.

When you declare a cursor variable as the formal parameter of a procedure, specify the IN OUT mode. That way, the procedure can return an open cursor to the caller. (Specifying the IN mode will be useful in future releases of PL/SQL, which will let you pass an open cursor to subprograms so that they can fetch from it.)
Unlike cursors, cursor variables do not take parameters. However, no flexibility is lost because you can pass whole queries (not just parameters) to a cursor variable. Also, the queries can reference bind variables and PL/SQL variables, parameters, and functions.

You use three statements to control a cursor variable: OPEN–FOR, FETCH, and CLOSE. First, you open a cursor variable for a multi–row query on the server side, fetch from it on the client side, then close it on either side.

You can use the cursor attributes %FOUND, %ISOPEN, %NOTFOUND, and %ROWCOUNT with cursor variables.

Currently, cursor variables are subject to the following restrictions, which will be lifted by future releases of PL/SQL:

- You cannot declare cursor variables in a package. However, you can define REF CURSOR types in a package.
- Remote subprograms cannot return the values of cursor variables. So, you cannot use a remote procedure to open a cursor variable.
- You cannot fetch from a cursor variable on the server side; you must fetch from it on the client side.
- The query associated with a cursor variable in an OPEN–FOR statement cannot be FOR UPDATE.
- You cannot use comparison operators to test cursor variables for equality, inequality, or nullity.
- You cannot assign nulls to a cursor variable.
- Cursors and cursor variables are not interoperable, meaning that you cannot use one where the other is expected.
- You cannot use a REF CURSOR type to specify the column type in a PL/SQL table, which means that rows in a PL/SQL table cannot store the values of cursor variables.
- You cannot use REF CURSOR types to specify column types in a CREATE TABLE or CREATE VIEW statement. So, database columns cannot store the values of cursor variables.
- You cannot use cursor variables with dynamic SQL.
Examples

In the following Pro*C example, you declare and initialize a cursor variable, then pass it to a PL/SQL block, which opens the cursor variable:

EXEC SQL BEGIN DECLARE SECTION;
...
/* Declare cursor variable. */
SQL_CURSOR emp_cur;
EXEC SQL END DECLARE SECTION;

/* Initialize cursor variable. */
EXEC SQL ALLOCATE :emp_cur;
EXEC SQL EXECUTE
BEGIN
/* Open cursor variable. */
OPEN :emp_cur FOR SELECT * FROM emp;
-- ^ bind variables must be prefixed with a colon
END;
END-EXEC;

To add flexibility, you can pass a host cursor variable and selector to a PL/SQL block that executes queries with different return types. As the following Pro*C example shows, a host cursor variable is compatible with any query return type:

EXEC SQL BEGIN DECLARE SECTION;
...
SQL_CURSOR generic_cv;
int choice;
EXEC SQL END DECLARE SECTION;
...
EXEC SQL ALLOCATE :generic_cv;
...
EXEC SQL EXECUTE
BEGIN
    IF :choice = 1 THEN
        OPEN :generic_cv FOR SELECT * FROM emp;
    ELSIF :choice = 2 THEN
        OPEN :generic_cv FOR SELECT * FROM dept;
    ELSIF :choice = 3 THEN
        OPEN :generic_cv FOR SELECT * FROM bonus;
    END IF;
END;
END-EXEC;
You can also pass a cursor variable to PL/SQL by calling a stored procedure that declares a cursor variable as one of its formal parameters. To centralize data retrieval, you can group type-compatible queries in a packaged procedure, as shown in the following example:

```
CREATE PACKAGE emp_data AS
    TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
    PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp,
                              choice IN NUMBER);
END emp_data;
```

```
CREATE PACKAGE BODY emp_data AS
    PROCEDURE open_emp_cv (emp_cv IN OUT EmpCurTyp,
                              choice IN NUMBER) IS
        BEGIN
            IF choice = 1 THEN
                OPEN emp_cv FOR SELECT * FROM emp WHERE comm IS NOT NULL;
            ELSIF choice = 2 THEN
                OPEN emp_cv FOR SELECT * FROM emp WHERE sal > 2500;
            ELSIF choice = 3 THEN
                OPEN emp_cv FOR SELECT * FROM emp WHERE deptno = 20;
            END IF;
        END IF;
    END open_emp_cv;
END emp_data;
```

Alternatively, you can use a standalone procedure to open the cursor variable. Simply define the REF CURSOR type in a separate package, then reference that type in the standalone procedure. For instance, if you create the following (bodiless) package, you can create standalone procedures that reference the types it defines:

```
CREATE PACKAGE cv_types AS
    TYPE EmpCurTyp IS REF CURSOR RETURN emp%ROWTYPE;
    TYPE DeptCurTyp IS REF CURSOR RETURN dept%ROWTYPE;
    TYPE BonusCurTyp IS REF CURSOR RETURN bonus%ROWTYPE;
    ...
END cv_types;
```

**Related Topics**
CLOSE, Cursors, FETCH, OPEN–FOR
DELETE Statement

Description
The DELETE statement removes entire rows of data from a specified table or view. For a full description of the DELETE statement, see Oracle7 Server SQL Reference.

Syntax
```
syntax = delete_statement ::=
    DELETE search_condition FROM cursor_name CURRENT OF table_reference alias
    WHERE search_condition CURRENT OF cursor_name ;

```
where `table_reference` stands for the following syntax:
```
syntax = schema. view @dblink
```

Keyword and Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>table_reference</code></td>
<td>This specifies a table or view, which must be accessible when you execute the DELETE statement, and for which you must have DELETE privileges.</td>
</tr>
<tr>
<td><code>alias</code></td>
<td>This is another (usually short) name for the referenced table or view and is typically used in the WHERE clause.</td>
</tr>
<tr>
<td><code>WHERE search_condition</code></td>
<td>This clause conditionally chooses rows to be deleted from the referenced table or view. Only rows that meet the <code>search_condition</code> are deleted. If you omit the WHERE clause, all rows in the table or view are deleted.</td>
</tr>
<tr>
<td><code>WHERE CURRENT OF cursor_name</code></td>
<td>This clause refers to the latest row processed by the FETCH statement associated with <code>cursor_name</code>. The named cursor must have been declared using the FOR UPDATE clause and must be open and positioned on a row. If the cursor is not open, the CURRENT OF clause causes an error.</td>
</tr>
</tbody>
</table>
Usage Notes

A `plsql_expression` (except one of type BOOLEAN) can be used in a DELETE statement wherever a literal can be used.

The DELETE WHERE CURRENT OF statement can be used after a fetch is executed on an open cursor (this includes implicit fetches executed in a cursor FOR loop), provided the associated query was declared with a FOR UPDATE clause. The DELETE WHERE CURRENT OF `cursor_name` deletes the current row; that is, the one just fetched.

The implicit SQL cursor and the cursor attributes `%NOTFOUND`, `%FOUND`, and `%ROWCOUNT` let you access useful information about the execution of a DELETE statement. For details, see “Managing Cursors” on page 4 – 10.

A DELETE statement might delete one or more rows or it might delete no rows. If one or more rows are deleted, you get the following results:

- `SQL%NOTFOUND` yields FALSE
- `SQL%FOUND` yields TRUE
- `SQL%ROWCOUNT` yields the number of rows deleted

If no rows are deleted, you get the following results:

- `SQL%NOTFOUND` yields TRUE
- `SQL%FOUND` yields FALSE
- `SQL%ROWCOUNT` yields 0

Examples

The following statement deletes from the `bonus` table all employees whose sales were below quota:

```
DELETE FROM bonus WHERE sales_amt < quota;
```
EXCEPTION_INIT Pragma

Description
EXCEPTION_INIT associates an exception name with an Oracle error number. That allows you to refer to any internal exception by name and to write a specific handler for it instead of using the OTHERS handler. For more information, see “Using EXCEPTION_INIT” on page 5 – 9.

Syntax
exception_initPragma ::= 
  PRAGMA EXCEPTION_INIT (exception_name, error_number) ;

Keyword and Parameter Description

PRAGMA
This keyword signifies that the statement is a pragma (compiler directive). Pragmas are processed at compile time, not at run time. They do not affect the meaning of a program; they simply convey information to the compiler.

exception_name
This is the name of an exception previously declared using an exception_declaration.

error_number
This is any valid Oracle error number. These are the same error numbers returned by the function SQLCODE.

Usage Notes
The pragma EXCEPTION_INIT must appear in the same declarative section as its associated exception, somewhere after the exception declaration. Thus, EXCEPTION_INIT can be used only in the declarative part of a PL/SQL block, subprogram, or package.

Be sure to assign only one exception name to an error number.

Example
DECLARE
  insufficient_privileges EXCEPTION;
  PRAGMA EXCEPTION_INIT (insufficient_privileges, -1031);
  /* Oracle returns error number -1031 if, for example, you try to UPDATE a table for which you have only SELECT privileges */
BEGIN
  ...
  EXCEPTION
    WHEN insufficient_privileges THEN
      /* handle the error */
END;

Related Topics
Exceptions, EXCEPTION_INIT, SQLCODE
Exceptions

Description
An exception is a runtime error or warning condition, which can be predefined or user-defined. Predefined exceptions are raised implicitly (automatically) by the runtime system. User-defined exceptions must be raised explicitly by RAISE statements. To handle raised exceptions, you write separate routines called exception handlers. For more information, see Chapter 5.

Syntax

```
exception_declaration ::= exception_name EXCEPTION ;
```

```
exception_handler ::= WHEN exception_name THEN seq_of_statements
                   OR
                   WHEN exception_name THEN seq_of_statements
                   OTHERS
```

Keyword and Parameter Description

```
exception_name
```
This is the name of a predefined or user-defined exception. For naming conventions, see “Identifiers” on page 2–4.

```
WHEN
```
This keyword introduces an exception handler. You can have multiple exceptions execute the same sequence of statements by following the keyword WHEN with a list of the exceptions, separating them by the keyword OR. If any exception in the list is raised, the associated statements are executed.

Each WHEN clause can associate a different sequence of statements with a list of exceptions. However, an exception name can appear only once in the exception-handling part of a PL/SQL block or subprogram.

```
OTHERS
```
This keyword stands for all the exceptions not explicitly named in the exception-handling part of the block. The use of OTHERS is optional and is allowed only as the last exception handler. You cannot include OTHERS in a list of exceptions following the keyword WHEN.

```
seq_of_statements
```
This construct represents a sequence of statements. For the syntax of `seq_of_statements`, see “Blocks” on page 9–10.
An exception declaration can appear only in the declarative part of a block, subprogram, or package. The scope rules for exceptions and variables are the same. But, unlike variables, exceptions cannot be passed as parameters to subprograms.

Some exceptions are predefined by PL/SQL. For a list of these exceptions, see “Predefined Exceptions” on page 5 – 5. PL/SQL declares predefined exceptions globally in package STANDARD, so you need not declare them yourself. Redeclaring predefined exceptions is error prone because your local declaration overrides the global declaration. In such cases, you must use dot notation to specify the predefined exception, as follows:

```
EXCEPTION
  WHEN invalid_number OR STANDARD.INVALID_NUMBER THEN
...
```

The exception–handling part of a PL/SQL block is optional. Exception handlers must come at the end of the block. They are introduced by the keyword EXCEPTION. The exception–handling part of the block is terminated by the same keyword END that terminates the entire block.

An exception should be raised only when an error occurs that makes it impossible or undesirable to finish processing. If there is no exception handler in the current block for a raised exception, the exception propagates according to the following rules:

- If there is an enclosing block for the current block, the exception is passed on to that block. The enclosing block then becomes the current block. If a handler for the raised exception is not found, the process repeats.
- If there is no enclosing block for the current block, an *unhandled exception* error is passed back to the host environment.

However, exceptions cannot propagate across remote procedure calls (RPCs). Therefore, a PL/SQL block cannot catch an exception raised by a remote subprogram. For a workaround, see “Using raise_application_error” on page 5 – 9.

Only one exception at a time can be active in the exception–handling part of a block. Therefore, if an exception is raised inside a handler, the block that encloses the current block is the first block searched to find a handler for the newly raised exception. From there on, the exception propagates normally.

An exception handler can reference only those variables that the current block can reference.
Example

DECLARE
  bad_employee_num  EXCEPTION;
  bad_act_num       EXCEPTION;
  ...
BEGIN
  ...
EXCEPTION
  WHEN bad_employee_num OR bad_acct_num THEN -- user defined
    ROLLBACK;
  WHEN ZERO_DIVIDE THEN -- a predefined exception
    INSERT INTO inventory_table VALUES (prod_name, quantity);
    COMMIT;
END;

Blocks, EXCEPTION_INIT, RAISE
EXIT Statement

Description
You use the EXIT statement to exit a loop. The EXIT statement has two forms: the unconditional EXIT and the conditional EXIT WHEN. With either form, you can name the loop to be exited. For more information, see “Iterative Control” on page 3 – 6.

Syntax
```
exit_statement ::=  

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>EXIT</td>
<td>label_name</td>
</tr>
<tr>
<td>[WHEN]</td>
<td>plsql_condition</td>
</tr>
<tr>
<td>;</td>
<td></td>
</tr>
</tbody>
</table>
```

Keyword and Parameter Description

EXIT
When the EXIT statement is processed and there is no label_name and no WHEN clause in the statement, PL/SQL exits the current loop immediately. Execution resumes with the statement following the loop.

label_name
This identifies the loop that you want to exit. You can use label_name to exit not only the current loop but any outer loop that encloses the current loop, providing the outer loop has been named in an enclosing loop_statement.

plsql_condition
This is a condition to be evaluated each time PL/SQL encounters the EXIT statement during normal execution of the sequence of statements in a loop. If plsql_condition yields TRUE, PL/SQL exits the current loop (or the loop labeled by label_name) immediately. This is equivalent to the following statement:

```
IF plsql_condition THEN EXIT; END IF;
```

The syntax of plsql_condition is defined in “Conditions” on page 9 – 20.

Usage Notes
An exit_statement can be used only within the seq_of_statements contained within loop_statement.

You can write an infinite loop in PL/SQL. For example, WHILE TRUE LOOP ... will never terminate in the normal way. In this case, you must use exit_statement to exit the loop.

If you use exit_statement to leave a cursor FOR loop prematurely, the cursor is closed automatically. The cursor is also closed automatically if an exception is raised inside the loop.
The EXIT statement in the following example is *illegal* because you cannot exit from a block directly; you can exit only from a loop:

```
DECLARE
    amount  NUMBER;
    maximum NUMBER;
BEGIN
    ...
    BEGIN
    ...
        IF amount >= maximum THEN
            EXIT;
        END IF;
    END;
    ...
END;
```

The following loop normally executes ten times, but it will exit prematurely if it finds no more data to return:

```
FOR i IN 1..10
    LOOP
        FETCH c1 INTO emp_rec;
        EXIT WHEN c1%NOTFOUND;
        total := total + emp_rec.comm;
    END LOOP;
```

The following example demonstrates the use of *label_name*:

```
<<outer>>
FOR i IN 1..10 LOOP
    ...
<<inner>>
FOR j IN 1..100 LOOP
    ...
    EXIT outer WHEN ... -- exits both loops
END LOOP inner;
END LOOP outer;
```
Expressions

Description
An expression is a combination of variables, constants, literals, operators, and function calls. (In some contexts, you can use host variables. For more information, see “Using Host Variables” on page 8–5.) The PL/SQL compiler determines the datatype of an expression from the types of the variables, constants, literals, and operators that comprise the expression. Every time the expression is evaluated, a single value of that type results. For more information, see “Expressions and Comparisons” on page 2–28.

Syntax

```
plsql_expression ::= 
  num_expression 
  | char_expression 
  | date_expression 
  | boolean_expression 

num_expression ::= 
  numeric_literal 
  | * numeric_variable 
  | / numeric_variable 
  | - numeric_variable 
  | + numeric_variable 
  | host_object_reference 
  | numeric_function_call 
  | NULL 
  | (num_expression) 
  | %ROWCOUNT 
  | cursor_name 
  | cursor_variable_name 
  | SQL 

char_expression ::= 
  char_literal 
  | char_variable 
  | host_object_reference 
  | char_function_call 
  | NULL 
  | (char_expression) 
```

Keyword and Parameter Description

boolean_expression  This is an expression that yields TRUE, FALSE, or NULL. For the syntax of boolean_expression, see “Conditions” on page 9–20.

num_expression:

numeric_literal    This is a numeric literal, or a literal that can be implicitly converted to a numeric value.

numeric_variable   This is the name of a previously declared variable or constant of type NUMBER or a type that can be implicitly converted to type NUMBER.

host_object_reference See “Host Objects” on page 9–43.

numeric_function_call This is a function call that returns a value of type NUMBER or of a type that can be implicitly converted to type NUMBER. Examples are the ABS, SQRT, and LENGTH functions.

NULL        This keyword represents a null. When used in a num_expression, the result is always a null.

integer_expr    This is a numeric expression with an integer value.

+, –  The symbols plus (+) and minus (–) are unary operators when used as the first characters in num_expression. The + has no effect. The – negates the value of num_expression. When used in num_expression, + and – are the addition and subtraction operators, respectively.

/, *, **  The symbols /, *, and ** are the division, multiplication, and exponentiation operators, respectively.
**char_expression:**

- **char_literal**: This is any valid string literal. For a definition of *string literal*, see “Literals” on page 9–64.

- **char_variable**: This is the name of a previously declared string variable or constant. For more information, see “Variables and Constants” on page 9–120.

- **host_object_reference**: See “Host Objects” on page 9–43.

- **char_function_call**: This is a function that returns a value of type CHAR. Examples are the **UPPER** and **SQLERRM** functions.

- **||**: The symbol **||** is the concatenation operator. The result of concatenating **string1** with **string2** is a character string that contains **string1** followed by **string2**. An example follows:

  `'Good' || 'Morning.'`  
  yields  
  `'Good Morning.'`

- **NULL**: This keyword represents a null. When used in concatenation, nulls have no effect on the result, as the next example shows:

  `'suit' || NULL || 'case'`  
  yields  
  `'suitcase'`

  A string zero characters in length ("") is called a null string and is treated like a null. An example follows:

  `'suit' || '' || 'case'`  
  yields  
  `'suitcase'`

**date_expression:**

- **date_literal**: This is a string literal that contains a valid date. For a definition of *string literal*, see “Literals” on page 9–64. A couple of examples follow:

  `'05–JUL–59'`
  
  `'02–DEC–77'`

- **date_variable**: This is the name of a previously declared variable or constant of type DATE or of a type that can be implicitly converted to type DATE.

- **host_object_reference**: See “Host Objects” on page 9–43.

- **date_function_call**: This is a function call that returns a value of type DATE or of a type that can be implicitly converted to type DATE. Examples are the **TO_DATE**, **LAST_DAY**, and **NEXT_DAY** functions.

- **NULL**: This keyword represents a null. When used in a *date_expression*, the result is always a null.
Host Objects

Objects from an external (host) environment are called *host objects*. For example, in the embedded PL/SQL environment, a variable declared in the host language is called a *host variable*. A form field in the Oracle Forms environment is another example of a host object. For more information, see “Using Host Variables” on page 8 – 5. The syntax of a *host_object_reference* follows:

```
host_object_reference ::= 
```

: **num_host_object**

This is the name of a previously declared object of type NUMBER or of a type that can be implicitly converted to type NUMBER.

: **char_host_object**

This is the name of a previously declared object of type CHAR or of a type that can be implicitly converted to type CHAR.

: **date_host_object**

This is the name of a previously declared object of type DATE or of a type that can be implicitly converted to type DATE. (An object of type CHAR in the default date format ‘DD-MON-YY’ would qualify.)

: **indicator**

This indicates the value or condition of a host variable. For example, in the embedded SQL environment, an integer *indicator variable* is used to assign nulls to input host variables and detect nulls or truncated values in output host variables. For more information, see “Using Indicator Variables” on page 8 – 10.

Usage Notes

The operations occur in their predefined order of precedence. From first to last (top to bottom), the default order of operations is as follows:

- parentheses
- exponents
- unary operators
- multiplication and division
- addition, subtraction, and concatenation

PL/SQL evaluates multiple operators of equal precedence in an undefined order.
When parentheses surround an expression that is part of a larger expression, the expression within the parentheses is evaluated first. The result is then used as a single value in the larger expression.

In a *plsql_expression*, you can use only values that have compatible datatypes. For more information, see “Datatype Conversion” on page 2–16.

### Examples

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>-- a num_expression with a numeric_literal</td>
</tr>
<tr>
<td>6 + b*4</td>
<td>-- a num_expression</td>
</tr>
<tr>
<td>‘JONES’</td>
<td>-- a char_expression with a character_literal</td>
</tr>
<tr>
<td>‘FAT’</td>
<td></td>
</tr>
<tr>
<td>last_name</td>
<td>-- a char_expression with a char_variable</td>
</tr>
<tr>
<td>‘26–NOV–65’</td>
<td>-- a date_expression that is a string literal</td>
</tr>
</tbody>
</table>

### FETCH Statement

**Description**

The FETCH statement retrieves rows of data one at a time from the active set, which consists of all rows that meet the search criteria of a multi-row query. The data is stored in variables or fields that correspond to the columns selected by the query. For more information, see “Processing Transactions” on page 4–35.

**Syntax**

```
fetch_statement ::= 
  FETCH cursor_name :cursor_variable_name record_name INTO variable_name;
```

- `cursor_name`: This is the name of a currently open explicit cursor. For naming conventions, see “Identifiers” on page 2–4.
- `cursor_variable_name`: This is the name of a cursor variable declared in a PL/SQL host environment and passed to PL/SQL as a bind variable. The datatype of the host cursor variable is compatible with the return type of any PL/SQL cursor variable. In SQL statements, host variables must be prefixed with a colon. For more information, see “Host Objects” on page 9–43.
- `variable_name`: This clause lists the scalar variables into which column values are fetched. All variables in the `variable_name` list must have been declared. For each column value returned by the query associated with the cursor or cursor variable, there must be a corresponding variable in the `variable_name` list. Also, their datatypes must be compatible. For more information, see “Datatype Conversion” on page 2–16.
- `record_name`: This clause specifies a record into which rows of values are fetched. For each column value returned by the query associated with the cursor or cursor variable, there must be a corresponding field in the record. Also, their datatypes must be compatible.
Usage Notes

You must use either a cursor FOR loop or the FETCH statement to process a multi–row query. With cursor variables, the FETCH statement must be executed on the client side.

Any variables in the WHERE clause of the query are evaluated only when the cursor or cursor variable is opened. To change the active set or the values of variables in the query, you must reopen the cursor or cursor variable with the variables set to their new values. To reopen a cursor, you must close it first. However, you need not close a cursor variable before reopening it.

You can use different INTO lists on separate fetches with the same cursor or cursor variable. Each fetch retrieves another row and assigns values to the target variables.

If you FETCH past the last row in the active set, the values of the target fields or variables are indeterminate and the %NOTFOUND attribute yields TRUE.

Eventually, the FETCH statement must fail to return a row; so when that happens, no exception is raised. In fact, FETCH can fail repeatedly without raising an exception. (Unlike the SELECT INTO statement, the FETCH statement never raises NO_DATA_FOUND.) So, whenever you place a FETCH statement inside a basic loop, include an EXIT WHEN statement. Otherwise, you have an infinite loop.

PL/SQL raises the predefined exception INVALID_CURSOR if you try to fetch from a closed or never–opened cursor.

Usually, you can use a cursor FOR loop instead of explicitly opening, fetching from, and closing a cursor.

Examples

The following cursor example shows that any variables in the WHERE clause are evaluated only when the cursor is opened:

```
DECLARE
    multiplied_sal NUMBER(10);
    multiplier     NUMBER(10) := 2;
    CURSOR my_cursor IS SELECT multiplier*sal FROM emp;
BEGIN
    OPEN my_cursor;    -- multiplier equals 2 here
    LOOP
        FETCH my_cursor INTO multiplied_sal;
        EXIT WHEN my_cursor%NOTFOUND;
        -- process the retrieved data
        multiplier := multiplier + 1;
        /* Doesn’t affect the FETCH. sal remains */
        /* multiplied by 2. */
    END LOOP;
END;
```
In the last example, all the retrieved values will equal 2 * sal, even though multiplier is incremented for each fetch (since the cursor was opened with multiplier set to 2). To change the active set or the values of variables in the query, you must close and reopen the cursor with the input variables (in this case, multiplier) set to their new values.

With cursor variables, the FETCH statement must be executed on the client side. In the following Pro*C example, you fetch rows into a host record (struct) named emp_rec:

```c
/* Exit loop when done fetching. */
EXEC SQL WHENEVER NOTFOUND DO break;
for (;;)
{
    /* Fetch row into record. */
    EXEC SQL FETCH :emp_cur INTO :emp_rec;
    /* process the data. */
}
```

The next example shows that you can use a different INTO clause on separate fetches with the same cursor variable. Each fetch retrieves another row from the same active set, as the following example shows:

```c
/* Exit loop when done fetching. */
EXEC SQL WHENEVER NOTFOUND DO break;
for (;;)
{
    /* Fetch row from active set. */
    EXEC SQL FETCH :emp_cur INTO :emp_rec1;
    /* Fetch next row from same active set. */
    EXEC SQL FETCH :emp_cur INTO :emp_rec2;
    /* process the data. */
}
```

%FOUND Attribute

Description

PL/SQL cursors and cursor variables have four attributes, including %FOUND, that give you useful information about the execution of a data manipulation statement. For more information, see “Using Cursor Attributes” on page 4–29.

There are two kinds of cursors: implicit and explicit. PL/SQL implicitly declares a cursor for all SQL data manipulation statements, including single-row queries. Until the SQL statement is executed, %FOUND yields NULL. Thereafter, %FOUND yields TRUE if an INSERT, UPDATE, or DELETE statement affected one or more rows, or a SELECT INTO statement returned one or more rows. Otherwise, %FOUND yields FALSE.

For multi-row queries, you can explicitly declare a cursor or cursor variable to process the rows. After the cursor or cursor variable is open but before the first fetch, %FOUND yields NULL. Thereafter, it yields TRUE if the last fetch returned a row, or FALSE if the last fetch failed to return a row.

Syntax

\[
\text{found\_attribute} ::= \\
\text{cursor\_name} \quad \%\text{FOUND} \quad \text{cursor\_variable\_name}
\]

Keyword and Parameter Description

cursor_name

This is the name of an explicit cursor or the implicit SQL cursor. For naming conventions, see “Identifiers” on page 2–4.

cursor_variable_name

This is the name of a PL/SQL cursor variable. The cursor variable name follows the usual scoping rules.

Usage Notes

You can use the %FOUND attribute in procedural statements but not in SQL statements. %FOUND is associated with every cursor or cursor variable. So, you can open multiple cursors or cursor variables, then use %FOUND to tell which cursors or cursor variables have rows left to fetch. If a cursor or cursor variable is not open, referencing it with %FOUND raises INVALID_CURSOR.

When an explicit cursor is opened, the rows that satisfy the associated query are identified and form the active set. Rows are fetched from the active set one at a time. %FOUND yields TRUE if the last fetch returned a row, or FALSE if the last fetch failed to return a row.
Examples

The block in the following example returns a number from each of two tables, then inserts the sum of the numbers into a third table. It completes when all rows have been fetched from either table.

```sql
-- available online in file EXAMP12
DECLARE
  CURSOR num1_cur IS SELECT num FROM num1_tab
    ORDER BY sequence;
  CURSOR num2_cur IS SELECT num FROM num2_tab
    ORDER BY sequence;
  num1     num1_tab.num%TYPE;
  num2     num2_tab.num%TYPE;
  pair_num NUMBER := 0;
BEGIN
  OPEN num1_cur;
  OPEN num2_cur;
  LOOP   -- loop through the two tables and get
    -- pairs of numbers
    FETCH num1_cur INTO num1;
    FETCH num2_cur INTO num2;
    IF (num1_cur%FOUND) AND (num2_cur%FOUND) THEN
      pair_num := pair_num + 1;
      INSERT INTO sum_tab VALUES (pair_num, num1 + num2);
    ELSE
      EXIT;
    END IF;
  END LOOP;
  CLOSE num1_cur;
  CLOSE num2_cur;
END;
```

In the next example, %FOUND is used to do an insert if an update succeeds:

```sql
UPDATE emp SET sal = sal * 1.1 WHERE ename = my_ename;
IF SQL%FOUND THEN
  INSERT INTO bonus_amts VALUES (my_deptno, my_ename, my_sal);
END IF;
```

Functions

Description

A function is a named program unit that takes parameters and returns a computed value. For more information, see “Functions” on page 6 – 5.

A function has two parts: the specification and the body. The function specification begins with the keyword FUNCTION and ends with the RETURN clause, which specifies the datatype of the result value. Parameter declarations are optional. Functions that take no parameters are written without parentheses.

The function body begins with the keyword IS and ends with the keyword END followed by an optional function name. The function body has three parts: a declarative part, an executable part, and an optional exception–handling part.

The declarative part contains declarations of types, cursors, constants, variables, exceptions, and subprograms. These objects are local and cease to exist when you exit the function. The executable part contains statements that assign values, control execution, and manipulate Oracle data. The exception–handling part contains exception handlers, which deal with exceptions raised during execution.

Syntax

function_specification ::= 
FUNCTION function_name ( parameter ) , function_name RETURN datatype_name ;
variable%TYPE
record_variable%TYPE
plsql_table%TYPE
table.column%TYPE
table%ROWTYPE
cursor%ROWTYPE
cursor_variable%ROWTYPE
function_declaration ::= function_body

function_body ::= 

FUNCTION function_name ( parameter ) 

RETURN datatype_name IS 

variable%TYPE 
record_variable%TYPE 
plsql_table%TYPE 
table.column%TYPE 
table%ROWTYPE 
cursor%ROWTYPE 
cursor_variable%ROWTYPE 

variable_declaration

cursor_declaration 
cursor_variable_declaration 
exception_declaration 
record_declaration 
plsql_table_declaration 

procedure_declaration 
function_declaration 

BEGIN sequence_of_statements

EXCEPTION exception_handler

END function_name ;
Keyword and Parameter Description

function_name
This is the name of a function. For naming conventions, see “Identifiers” on page 2–4.

parameter_name
This is the name of a formal parameter, which is a variable declared in a function specification and referenced in the function body. For naming conventions, see “Identifiers” on page 2–4.

RETURN
This keyword introduces the RETURN clause, which specifies the datatype of the result value.

type_name
This specifies the datatype of a formal parameter or result value. For more information, see “Datatypes” on page 2–9. The datatype specifier in a parameter declaration must be unconstrained.

table.column
This refers to a database table and column that must be accessible when the declaration is elaborated.

table
This refers to a database table that must be accessible when the declaration is elaborated.

%TYPE
This attribute provides the datatype of a variable or database column.

%ROWTYPE
This attribute provides a record that represents a row in a database table. Columns in a row and corresponding fields in a record have the same names and datatypes.

variable_declaration
This construct declares a variable. For the syntax of variable_declaration, see “Variables and Constants” on page 9–120.
constant_declaration This construct declares a constant. For the syntax of constant_declaration, see "Variables and Constants" on page 9 – 120.
cursor_declaration This construct declares an explicit cursor. For the syntax of cursor_declaration, see "Cursors" on page 9 – 23.
cursor_variable_declaration This construct declares a cursor variable. For the syntax of cursor_variable_declaration, see "Cursor Variables" on page 9 – 27.
exception_declaration This construct declares an exception. For the syntax of exception_declaration, see "Exceptions" on page 9 – 35.
record_declaration This construct declares a user-defined record. For the syntax of record_declaration, see "Records" on page 9 – 94.
plsql_table_declaration This construct declares a PL/SQL table. For the syntax of plsql_table_declaration, see "PL/SQL Tables" on page 2 – 38.
procedure_declaration This construct declares a procedure. For the syntax of procedure_declaration, see "Procedures" on page 9 – 88.
function_declaration This construct declares a nested function.
seq_of_statements This represents a sequence of statements. For the syntax of seq_of_statements, see "Blocks" on page 9 – 10.
exception_handler This construct associates an exception with a sequence of statements, which is executed when that exception is raised. For the syntax of exception_handler, see "Exceptions" on page 9 – 35.
IN, OUT, IN OUT These parameter modes define the behavior of formal parameters. The IN parameter mode lets you pass values to the subprogram being called. An OUT parameter lets you return values to the caller of the subprogram. An IN OUT parameter lets you pass initial values to the subprogram being called and return updated values to the caller.
DEFAULT or := This keyword or assignment operator allows you to initialize IN parameters to default values.
plsql_expression This is an arbitrarily complex expression, which is used to initialize a parameter. The syntax of plsql_expression is defined in "Expressions" on page 9 – 40. The value of plsql_expression is assigned to the parameter identified by parameter_name. The datatype of plsql_expression must be compatible with the datatype of the parameter. For more information, see "Datatype Conversion" on page 2 – 16.
Every function must contain at least one RETURN statement. Otherwise, PL/SQL raises the predefined exception PROGRAM_ERROR at run time.

A function is called as part of an expression. For example, the function sal_ok might be called as follows:

```
promotable := sal_ok(new_sal, new_title) AND (rating > 3);
```

You can write the function specification and body as a unit. Or, you can separate the function specification from its body. That way, you can hide implementation details by placing the function in a package.

You can define functions in a package body without declaring their specifications in the package specification. However, such functions can be called only from inside the package.

Inside a function, an IN parameter acts like a constant. Therefore, it cannot be assigned a value. An OUT parameter acts like an uninitialized variable. So, its value cannot be assigned to another variable or reassigned to itself. An IN OUT parameter acts like an initialized variable. Therefore, it can be assigned a value, and its value can be assigned to another variable. For summary information about the parameter modes, see Table 6–1 on page 6 – 15.

Avoid using the OUT and IN OUT modes with functions. The purpose of a function is to take zero or more parameters and return a single value. It is poor programming practice to have a function return multiple values. Also, functions should be free from side effects, which change the values of variables not local to the subprogram. Thus, a function should not change the values of its actual parameters.

Functions can be defined using any Oracle tool that supports PL/SQL. To become available for general use, however, functions must be CREATEd and stored in an Oracle database.

You can issue the CREATE FUNCTION statement interactively from SQL*Plus or Server Manager. For the full syntax of the CREATE statement, see Oracle7 Server SQL Reference.

The following function returns the balance of a specified bank account:

```
FUNCTION balance (acct_id INTEGER) RETURN REAL IS
  acct_bal  REAL;
BEGIN
  SELECT bal INTO acct_bal FROM accts WHERE acctno = acct_id;
  RETURN acct_bal;
END balance;
```

GOTO Statement

Description
The GOTO statement branches to a labeled statement or PL/SQL block unconditionally. The label must be unique within its scope and must precede an executable statement or a PL/SQL block. When executed, the GOTO statement transfers control to the labelled statement or block. For more information, see “GOTO Statement” on page 3 – 14.

Syntax
```
label_name_declaration ::= 

<< label_name >>

goto_statement ::= 

GOTO label_name

```

Keyword and Parameter Description

label_name
This is an undeclared identifier that optionally labels a statement or block to which you want to transfer control. For naming conventions, see “Identifiers” on page 2 – 4.

You use label_name in a GOTO statement to transfer control to the statement or block following <<label_name>>. For more information about label_name, see “Blocks” on page 9 – 10.

Usage Notes
Some possible destinations of a GOTO statement are illegal. In particular, a GOTO statement cannot branch into an IF statement, LOOP statement, or sub–block. For example, the following GOTO statement is illegal:

```
BEGIN
...
    GOTO update_row;  -- illegal
...
    IF valid THEN
    ...
    <<update_row>>
    UPDATE emp SET ...
    END IF;
END;
```

From the current block, a GOTO statement can branch to another place in the block or into an enclosing block, but not into an exception handler. From an exception handler, a GOTO statement can branch into an enclosing block, but not into the current block.
If you use the GOTO statement to leave a cursor FOR loop prematurely, the cursor is closed automatically. The cursor is also closed automatically if an exception is raised inside the loop.

A given label_name can appear at most once in a block, although it can appear in other blocks, including enclosing blocks and sub-blocks. If label_name does not appear in the current block, the GOTO statement branches to the first enclosing block in which label_name appears.

**Examples**

A GOTO statement cannot be used to label just any keyword. It must label an executable statement or a block. For example, the following GOTO statement is illegal:

```
BEGIN
  ...
  FOR ctr IN 1..50 LOOP
    DELETE FROM emp WHERE ...
    IF SQL%FOUND THEN GOTO end_loop; END IF;
    ...
  <<-end_loop>>
  END LOOP;  -- not an executable statement
END;
```

To debug the last example, simply add the NULL statement, as follows:

```
BEGIN
  ...
  FOR ctr IN 1..50 LOOP
    DELETE FROM emp WHERE ...
    IF SQL%FOUND THEN GOTO end_loop; END IF;
    ...
  <<-end_loop>>
  NULL;  -- an executable statement that specifies inaction
  END LOOP;
END;
```

You cannot branch into an IF statement, so the following GOTO statement is illegal:

```
BEGIN
  ...
  GOTO my_label;  -- illegal
  IF a > b THEN
    b := b - c;
  <<-my_label>>
    x := x + 1;
  END IF;
END;
```

For more examples of legal and illegal GOTO statements, see “GOTO Statement” on page 3 – 14.
IF Statement

Description
The IF statement lets you execute a sequence of statements conditionally. That is, whether the sequence is executed or not depends on the value of a condition. For more information, see “Conditional Control” on page 3–2.

Syntax
if_statement ::= IF plsql_condition THEN seq_of_statements THEN ELSEIF plsql_condition THEN seq_of_statements ELSE seq_of_statements END IF ;

Keyword and Parameter Description

plsql_condition This is a condition associated with a sequence of statements, which is executed only if the condition yields TRUE. For the syntax of plsql_condition, see “Conditions” on page 9–20.

seq_of_statements This represents a sequence of statements. For the syntax of seq_of_statements, see “Blocks” on page 9–10.

THEN This keyword associates the condition that precedes THEN with the seq_of_statements that follows. If the condition yields TRUE, the associated seq_of_statements is executed.

ELSIF This keyword introduces a condition to be evaluated if the condition following IF and all the conditions following any preceding ELSIFs yield FALSE or NULL.

ELSE No condition follows this keyword. If control reaches the keyword ELSE, the seq_of_statements that follows is executed.
There are three forms of IF statements: IF–THEN, IF–THEN–ELSE, and IF–THEN–ELSIF. The simplest form of IF statement associates a condition with a sequence of statements enclosed by the keywords THEN and END IF. The sequence of statements is executed only if the condition yields TRUE. If the condition yields FALSE or NULL, the IF statement does nothing. In either case, control passes to the next statement.

The second form of IF statement adds the keyword ELSE followed by an alternative sequence of statements. The sequence of statements in the ELSE clause is executed only if the condition yields FALSE or NULL. Thus, the ELSE clause ensures that a sequence of statements is executed.

The third form of IF statement uses the keyword ELSIF to introduce additional conditions. If the first condition yields FALSE or NULL, the ELSIF clause tests another condition. An IF statement can have any number of ELSIF clauses; the final ELSE clause is optional. Conditions are evaluated one by one from top to bottom. If any condition yields TRUE, its associated sequence of statements is executed and control passes to the next statement. If all conditions yield FALSE or NULL, the sequence in the ELSE clause is executed.

An IF statement never executes more than one sequence of statements because processing is complete after a sequence of statements is executed.

The THEN and ELSE clauses can include IF statements. That is, IF statements can be nested.

In the example below, if shoe_count has a value of 10, both the first and second conditions are true. Nevertheless, order_quantity is assigned the proper value of 50 because processing of an IF statement stops after a condition yields TRUE and its associated seq_of_statements is executed. The condition associated with ELSIF is never evaluated and control passes to the INSERT statement.

```sql
IF shoe_count < 20 THEN
    order_quantity := 50;
ELSIF shoe_count < 30 THEN
    order_quantity := 20;
ELSE
    order_quantity := 10;
END IF;
INSERT INTO purchase_order VALUES (shoe_type, order_quantity);
```
In the following example, depending on the value of score, one of three status messages is inserted into the grades table:

```sql
IF score < 70 THEN
    fail := fail + 1;
    INSERT INTO grades VALUES (student_id, 'Failed');
ELSIF score IS NULL THEN
    INSERT INTO grades VALUES (student_id, 'Unknown');
ELSE
    pass := pass + 1;
    INSERT INTO grades VALUES (student_id, 'Passed');
END IF;
```
**INSERT Statement**

**Description**

The INSERT statement adds new rows of data to a specified database table or view. For a full description of the INSERT statement, see Oracle7 Server SQL Reference.

**Syntax**

```plaintext
INSERT INTO table_reference (column_name, ...
VALUES (sql_expression, ...
```

where `table_reference` stands for the following syntax:

- `schema.`
- `table`
- `view`
- `@dblink`

**Keyword and Parameter Description**

- **table_reference**: This specifies a table or view, which must be accessible when you execute the INSERT statement, and for which you must have INSERT privileges.
- **alias**: This is another (usually short) name for the referenced table or view and is typically used in the WHERE clause of the subquery.
- **column_name**: This is the name of a column in the table or view into which data is inserted. Column names must not be specified more than once in the `column_name` list and need not appear in the order in which they were defined by the CREATE TABLE or CREATE VIEW statement. If a `column_name` list does not include all the columns in a table, the excluded columns are set to NULL or to a default value specified in the CREATE TABLE statement.
- **VALUES (sql_expression, sql_expression, ...)**: This clause assigns the values of `sql_expression`s in the VALUES list to corresponding columns in the column list. If no column list is supplied, the first value is inserted into the first column defined by the CREATE TABLE statement, the second value is inserted into the second column, and so on. A `sql_expression` is any expression valid in SQL. For more information, see Oracle7 Server SQL Reference.
There must be only one value for each `column_name` in the column list. The first value is associated with the first column name, the second value is associated with the second column name, and so on. If there is no column list, a value must be supplied for each column in the table.

The datatypes of the values being inserted must be compatible with the datatypes of the corresponding columns in the column list. For more information, see “Datatypes” on page 2–10.

**select_statement**

This is a query that returns a set of values for insertion into a database table (or view). The syntax of `select_statement` is similar to the syntax of `select_into_statement` defined in “SELECT INTO Statement” on page 9–107, except that `select_statement` cannot have an INTO clause.

As many rows are added to the table as are returned by `select_statement`. The query must return a value for every column in the column list or for every column in the table if no column list is supplied. As with the VALUES clause, there is a positional, one-to-one correspondence between select-items and the columns in the column list.

**Usage Notes**

All character and date literals in the VALUES list must be enclosed by single quotes ('). Numeric literals are not enclosed by quotes.

The implicit SQL cursor and cursor attributes (%NOTFOUND, %FOUND, %ROWCOUNT, and %ISOPEN) let you access useful information about the execution of an INSERT statement. For more information, see “Managing Cursors” on page 4–10.

An INSERT statement might insert one or more rows, or it might insert no rows. If one or more rows are inserted, you get the following results:

- SQL%NOTFOUND yields FALSE
- SQL%FOUND yields TRUE
- SQL%ROWCOUNT yields the number of rows inserted

If no rows are inserted, you get the following results:

- SQL%NOTFOUND yields TRUE
- SQL%FOUND yields FALSE
- SQL%ROWCOUNT yields 0
Examples

```
INSERT INTO bonus SELECT ename, job, sal, comm FROM emp
    WHERE comm > sal * 0.25;

INSERT INTO emp (empno, ename, job, sal, comm, deptno)
    VALUES (4160, 'STURDEVIN', 'SECURITY GUARD', 2045, NULL, 30);

DECLARE
    my_deptno  NUMBER;
    my_dname   CHAR(15);
BEGIN
    my_deptno := 70;
    my_dname := 'Distribution';
    INSERT INTO dept
        VALUES (my_deptno, UPPER(my_dname), 'CHICAGO');
END;
```
%ISOPEN Attribute

Description
PL/SQL cursors and cursor variables have four attributes, including %ISOPEN, that give you useful information about the cursor or cursor variable. For more information, see “Using Cursor Attributes” on page 4 – 29.

There are two kinds of cursors: implicit and explicit. PL/SQL implicitly declares a cursor for all SQL data manipulation statements, including single-row queries. Oracle automatically closes the SQL cursor after executing its associated SQL statement, so %ISOPEN always yields FALSE.

For multi-row queries, you can explicitly declare a cursor or cursor variable to process the rows. %ISOPEN yields TRUE if the cursor or cursor variable is open; otherwise, %ISOPEN yields FALSE.

Syntax
```plaintext
isopen_attribute ::=  
  cursor_name %ISOPEN  
  cursor_variable_name
```

Keyword and Parameter Description

cursor_name
This is the name of an explicit cursor or the implicit SQL cursor. For naming conventions, see “Identifiers” on page 2 – 4.

cursor_variable_name
This is the name of a PL/SQL cursor variable. The cursor variable name follows the usual scoping rules.

Usage Notes
You can use the %ISOPEN attribute in procedural statements but not in SQL statements. %ISOPEN is associated with every cursor or cursor variable. So, you can use the %ISOPEN attribute to check the status of the cursor or cursor variable. However, with the implicit SQL cursor, %ISOPEN always yields FALSE.

Example
```plaintext
IF NOT (my_cursor%ISOPEN) THEN  
  OPEN my_cursor;  
END IF;  
FETCH my_cursor INTO ... 
```

Literals

Description

A literal is an explicit numeric, character, string, or Boolean value not represented by an identifier. The numeric literal 135 and the string literal 'hello world' are examples. For more information, see “Literals” on page 2 – 7.

Syntax

- **numeric_literal** ::= 
  - integer  
  - real_number

- **integer** ::= 
  - digit

- **real_number** ::= 
  - integer 
  - E

- **character_literal** ::= 
  - 'char'

- **string_literal** ::= 
  - 'char'

- **boolean_literal** ::= 
  - TRUE
  - FALSE
  - NULL
Keyword and Parameter Description

integer
This is an optionally signed whole number without a decimal point.

real_number
This is an optionally signed whole or fractional number with a decimal point.

digit
This must be one of the numerals 0..9.

char
This is a member of the PL/SQL character set. For more information, see “Character Set” on page 2–2.

TRUE, FALSE
This is a predefined Boolean value.

NULL
This is a predefined non-value, which stands for a missing, unknown, or inapplicable value.

Usage Notes
Two kinds of numeric literals can be used in arithmetic expressions: integers and reals. Numeric literals must be separated by punctuation. Space characters can be used in addition to the punctuation.

A character literal is an individual character enclosed by single quotes (apostrophes). Character literals include all the printable characters in the PL/SQL character set: letters, numerals, spaces, and special symbols. PL/SQL is case sensitive within character literals. So, for example, PL/SQL considers the literals ‘Q’ and ‘q’ to be different.

A string literal is a sequence of zero or more characters enclosed by single quotes. The null string (""") contains zero characters. To represent an apostrophe within a string, write two single quotes. PL/SQL is case sensitive within string literals. So, for example, PL/SQL considers the literals ‘white’ and ‘White’ to be different.

Also, trailing blanks are significant within string literals, so ‘White’ and ‘White ’ are different. How a string literal compares to a variable does not depend on the variable; trailing blanks in a literal are never trimmed.

Unlike the non-value NULL, the Boolean values TRUE and FALSE cannot be inserted into a database column.
Examples

Several examples of numeric literals follow:

25   6.34   7E2   25e-03   .1   1.   +17   -4.4

Several examples of character literals follow:

'H'   'k'   ' '   '9'   ']'   'g'

A few examples of string literals follow:

'$$5,000$
'02-AUG-87'
'Don’t leave without saving your work.'

Variables and Constants
LOCK TABLE Statement

Description
The LOCK TABLE statement lets you lock entire database tables in a specified lock mode so that you can share or deny access to tables while maintaining their integrity. For more information, see “Using LOCK TABLE” on page 4 – 42.

Syntax
lock_table_statement ::= 

---

  LOCK TABLE [table_reference] MODE lock_mode [NOWAIT] ;

---

where table_reference stands for the following syntax:

---

  [schema.]table [view] [@dblink]

---

Keyword and Parameter Description

- **table_reference**: The table or view specified by table_reference must be accessible when you execute the LOCK TABLE statement.

- **lock_mode**: This parameter specifies the lock mode. It must be one of the following: ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE, SHARE, SHARE ROW EXCLUSIVE, or EXCLUSIVE.

- **NOWAIT**: This optional keyword tells Oracle not to wait if the table has been locked by another user. Control is immediately returned to your program, so it can do other work before trying again to acquire the lock.

Usage Notes
If you omit the keyword NOWAIT, Oracle waits until the table is available; the wait has no set limit. Table locks are released when your transaction issues a commit or rollback. For more information, see Oracle7 Server SQL Reference.

A table lock never keeps other users from querying a table, and a query never acquires a table lock. Only if two different transactions try to modify the same row will one transaction wait for the other to complete.
If your program includes SQL locking statements, make sure the Oracle users requesting locks have the privileges needed to obtain the locks. Your DBA can lock any table. Other users can lock tables they own or tables for which they have a privilege, such as SELECT, INSERT, UPDATE, or DELETE.

**Example**

The following statement locks the *accts* table in shared mode:

```
LOCK TABLE accts IN SHARE MODE;
```
LOOP Statement

Description
The LOOP statement executes a sequence of statements multiple times. The loop encloses the sequence of statements that is to be repeated. PL/SQL supports the following kinds of loops:

- basic loops
- WHILE loops
- numeric FOR loops
- cursor FOR loops

For more information, see “Iterative Control” on page 3 – 6.

Syntax

```
loop_statement ::= 

<<<label_name>>>
  WHILE plsql_condition
  FOR numeric_loop_param
  cursor_loop_param

  seq_of_statements
  END LOOP
  
  label_name

numeric_loop_param ::= 

index IN 
  REVERSE
  integer_expr .. integer_expr

cursor_loop_param ::= 

record_name IN cursor_name

select_statement
```

Keyword and Parameter Description

label_name
This is an undeclared identifier, which optionally labels a loop. For naming conventions, see “Identifiers” on page 2 – 4. If used, label_name must be enclosed by double angle brackets and must appear at the beginning of the LOOP statement. Optionally, label_name can also appear at the end of the LOOP statement.
You can use label_name in an EXIT statement to exit the loop labeled by label_name.

You cannot reference the index of an outer loop from an inner (nested) loop if both indexes have the same name—unless the outer loop is labeled by label_name and you use dot notation, as follows:

label_name.index_name

In the following example, you compare two loop indexes that have the same name, one used by an enclosing loop, the other by a nested loop:

<<outer>>
FOR ctr IN 1..20 LOOP
  ...
<<inner>>
  FOR ctr IN 1..10 LOOP
    IF outer.ctr > ctr THEN ...  
     ...
  END LOOP inner;
END LOOP outer;

This represents a sequence of statements to be repeated. For the syntax of seq_of_statements, see “Blocks” on page 9–10.

Basic Loops

The simplest form of LOOP statement is the basic (or infinite) loop, which encloses a sequence of statements between the keywords LOOP and END LOOP. With each iteration of the loop, the sequence of statements is executed, then control resumes at the top of the loop. If further processing is undesirable or impossible, you can use the EXIT, GOTO, or RAISE statement to complete the loop. A raised exception will also complete the loop.

WHILE Loops

WHILE plsql_condition

The WHILE–LOOP statement associates a condition with a sequence of statements enclosed by the keywords LOOP and END LOOP. Before each iteration of the loop, the condition is evaluated. If the condition yields TRUE, the sequence of statements is executed, then control resumes at the top of the loop. If the condition yields FALSE or NULL, the loop is bypassed and control passes to the next statement. For the syntax of plsql_condition, see “Conditions” on page 9–20.
Numeric FOR Loops

FOR numeric_loop_param

Whereas the number of iterations through a WHILE loop is unknown until the loop completes, the number of iterations through a FOR loop is known before the loop is entered. Numeric FOR loops iterate over a specified range of integers. (Cursor FOR loops, which iterate over the active set of a cursor, are discussed later.) The range is part of an iteration scheme, which is enclosed by the keywords FOR and LOOP.

The range is evaluated when the FOR loop is first entered and is never re-evaluated. The seq_of_statements is executed once for each integer in the range defined by integer_expr..integer_expr. After each iteration, the loop index is incremented.

index

This is the name of a loop index. For naming conventions, see “Identifiers” on page 2–4.

You need not declare index. It is implicitly declared as a variable of type INTEGER. The scope of index is the loop itself. Therefore, you cannot access its value outside the loop.

The implicit declaration of index overrides any other declaration outside the loop. So, a variable declared with the same name as index outside the loop cannot be referenced inside the loop unless a label is used, as follows:

```sql
<<main>>
DECLARE
    num NUMBER;
BEGIN
    ...
    FOR num IN 1..10 LOOP
        ...
        IF main.num > 5 THEN -- refers to the variable num, -- not to the loop index
            END IF;
        END LOOP;
END main;
```

Inside the loop, index is treated like a constant. It can appear in expressions, but you cannot assign it a value.
This is an expression that evaluates to an integer. The expression is evaluated only when the loop is first entered.

By default, index is assigned the value of the left integer_expr. If it is not greater than the right integer_expr, the seq_of_statements is executed, then index is incremented. If index is still not greater than the right integer_expr, the seq_of_statements is executed again. The process repeats until index is greater than the right integer_expr. At this point, the loop completes.

REVERSE

By default, iteration proceeds upward from the lower bound to the higher bound. However, if you use the keyword REVERSE, iteration proceeds downward from the higher bound to the lower bound. After each iteration, the loop index is decremented.

The index is assigned the value of the right integer_expr. If it is not less than the left integer_expr, the seq_of_statements is executed, then index is decremented. If index is still not less than the left integer_expr, the seq_of_statements is executed again. The process repeats until index is less than the left integer_expr, at which point the loop completes. An example follows:

```
FOR i IN REVERSE 1..10 LOOP  -- i starts at 10, ends at 1
    -- statements here execute 10 times
END LOOP;
```

Cursor FOR Loops

A cursor FOR loop implicitly declares its loop index as a %ROWTYPE record, opens a cursor, repeatedly fetches rows of values from the active set into fields in the record, and closes the cursor when all rows have been processed.

When a cursor FOR loop is entered, an implicit OPEN cursor_name is executed. Then, for each row that satisfies the query associated with the cursor, an implicit FETCH is done into the implicitly declared record_name and the seq_of_statements is executed. When there are no more rows left to fetch, an implicit CLOSE cursor_name is executed and the loop completes. Thus, the seq_of_statements is executed once for each row that satisfies the query associated with cursor_name.

This is the name of an implicitly declared record. For naming conventions, see “Identifiers” on page 2 – 4.

The record has the same structure as a row retrieved by cursor_name and is equivalent to a record explicitly declared as follows:

```
record_name  cursor_name%ROWTYPE;
```
The record is defined only inside the loop. You cannot refer to its fields outside the loop. The implicit declaration of `record_name` overrides any other declaration outside the loop. So, a record variable declared with the same name as `record_name` outside the loop cannot be referenced inside the loop unless a label is used.

Fields in the record hold column values from the implicitly fetched row. The fields have the same names and datatypes as their corresponding columns. To access field values, you use dot notation, as follows:

```
record_name.column_name
```

Select-items fetched from the FOR loop cursor must have simple names or, if they are expressions, must have aliases. In the next example, `wages` is an alias for the select-item `sal+NVL(comm,0)`:

```
CURSOR c1 IS SELECT empno, sal+NVL(comm,0) wages, job ...
```

`cursor_name` This is the name of a previously declared cursor. For naming conventions, see “Identifiers” on page 2–4.

When the cursor FOR loop is entered, `cursor_name` cannot refer to a cursor that was already opened by an OPEN statement or an enclosing cursor FOR loop.

`parameter` This is the name of a formal cursor parameter. For naming conventions, see “Identifiers” on page 2–4.

The syntax of `parameter` is the same as the syntax of `plsql_expression`, which is defined in “Expressions” on page 9–40.

If formal parameters are declared, actual parameters must be passed to the cursor. The values of actual parameters are used when the cursor is opened. The datatypes of the actual parameters must be compatible with the datatypes of the corresponding formal parameters. For more information, see “Datatypes” on page 2–10.

`select_statement` This is a query associated with an internal cursor unavailable to you. PL/SQL automatically declares, opens, fetches from, and closes the internal cursor. Because `select_statement` is not an independent statement, the implicit SQL cursor does not apply to it.

The syntax of `select_statement` is similar to the syntax of `select_into_statement` defined in “SELECT INTO Statement” on page 9–107, except that `select_statement` cannot have an INTO clause.
Usage Notes

You can use the EXIT WHEN statement to exit any loop prematurely. If the condition in the WHEN clause yields TRUE, you exit the loop immediately. For more information, see “EXIT Statement” on page 9 – 38.

When you leave a cursor FOR loop, the cursor is closed automatically even if you use an EXIT or GOTO statement to leave the loop prematurely. The cursor is also closed automatically if an exception is raised inside the loop.

Example

```
DECLARE
    bonus  REAL;
    CURSOR c1 IS SELECT empno, sal, comm FROM emp;
BEGIN
    FOR c1rec IN c1 LOOP
        bonus := (c1rec.sal * 0.05) + (c1rec.comm * 0.25);
        INSERT INTO bonuses VALUES (c1rec.empno, bonus);
    END LOOP;
    COMMIT;
END;
```

%NOTFOUND Attribute

Description
PL/SQL cursors and cursor variables have four attributes, including %NOTFOUND, that give you useful information about the execution of a data manipulation statement. For more information, see “Using Cursor Attributes” on page 4 – 29.

There are two kinds of cursors: implicit and explicit. PL/SQL implicitly declares a cursor for all SQL data manipulation statements, including single-row queries. Until the SQL statement is executed, %NOTFOUND yields NULL. Thereafter, %NOTFOUND yields FALSE if an INSERT, UPDATE, or DELETE affected one or more rows or a SELECT INTO returned one or more rows. Otherwise, %NOTFOUND yields TRUE.

For multi-row queries, you can explicitly declare a cursor or cursor variable to process the rows. After the cursor or cursor variable is open but before the first fetch, %NOTFOUND yields NULL. Thereafter, it yields FALSE if the last fetch returned a row, or TRUE if the last fetch failed to return a row.

Syntax

```
notfound_attribute ::=  
  cursor_name  %NOTFOUND(cursor_variable_name)
```

Keyword and Parameter Description

cursor_name
This is the name of an explicit cursor or the implicit SQL cursor. For naming conventions, see “Identifiers” on page 2 – 4.

cursor_variable_name
This is the name of a PL/SQL cursor variable. The cursor variable name follows the usual scoping rules.

Usage Notes
You can use the %NOTFOUND attribute in procedural statements but not in SQL statements. %NOTFOUND is associated with every cursor or cursor variable. So, you can open multiple cursors or cursor variables, then use %NOTFOUND to tell which cursors or cursor variables have rows left to fetch. If a cursor or cursor variable is not open, referencing it with %NOTFOUND raises INVALID_CURSOR.

When a cursor or cursor variable is opened, the rows that satisfy the associated query are identified and form the active set. Rows are fetched from the active set one at a time. %NOTFOUND yields FALSE if the last fetch returned a row, or TRUE if the last fetch failed to return a row.
In the following example, %NOTFOUND is used to raise an exception if a deletion fails:

```sql
DELETE FROM parts WHERE status = 'OBSOLETE';
IF SQL%NOTFOUND THEN
   RAISE none_purged;
END IF;
```

The block in the next example returns a number from each of two tables, then inserts the sum of the numbers into a third table. It completes when all rows have been fetched from either of the two tables.

```sql
-- available online in file EXAMP13
DECLARE
   CURSOR num1_cur IS SELECT num FROM num1_tab
      ORDER BY sequence;
   CURSOR num2_cur IS SELECT num FROM num2_tab
      ORDER BY sequence;
   num1       num1_tab.num%TYPE;
   num2       num2_tab.num%TYPE;
   pair_num   NUMBER := 0;
BEGIN
   OPEN num1_cur;
   OPEN num2_cur;
   LOOP -- loop through the two tables and get
      -- pairs of numbers
      FETCH num1_cur INTO num1;
      FETCH num2_cur INTO num2;
      EXIT WHEN (num1_cur%NOTFOUND) OR (num2_cur%NOTFOUND);
      pair_num := pair_num + 1;
      INSERT INTO sum_tab VALUES (pair_num, num1 + num2);
   END LOOP;
   CLOSE num1_cur;
   CLOSE num2_cur;
END;
```

CLOSE, Cursors, Cursor Variables, DELETE, FETCH, %FOUND, INSERT, OPEN, SELECT INTO, UPDATE
NULL Statement

Description
The NULL statement explicitly specifies inaction; it does nothing other than pass control to the next statement. In a construct allowing alternative actions, the NULL statement serves as a placeholder. For more information, see “NULL Statement” on page 3–17.

Syntax
null_statement ::= 

Usage Notes
The NULL statement improves readability by making the meaning and action of conditional statements clear. It tells readers that the associated alternative has not been overlooked, but that indeed no action is necessary.

Each clause in an IF statement must contain at least one executable statement. The NULL statement meets this requirement. So, you can use the NULL statement in clauses that correspond to circumstances in which no action is taken.

Do not confuse the NULL statement with the Boolean non–value NULL; they are unrelated.

Examples
In the following example, the NULL statement emphasizes that only salespeople receive commissions:

```sql
IF job_title = ‘SALESPERSON’ THEN
  compute_commission(emp_id);
ELSE
  NULL;
END IF;
```

In the next example, the NULL statement shows that no action is taken for unnamed exceptions:

```sql
EXCEPTION
  WHEN ZERO_DIVIDE THEN
    ROLLBACK;
... WHEN OTHERS THEN
  NULL;
END;
```
OPEN Statement

Description
The OPEN statement executes the multi-row query associated with an explicit cursor. It also allocates resources used by Oracle to process the query and identifies the active set, which consists of all rows that meet the query search criteria. The cursor is positioned before the first row in the active set. For more information, see “Processing Transactions” on page 4 – 35.

Syntax
open_cursor_statement ::= 

OPEN cursor_name [ , input_parameter ]

Keyword and Parameter Description

cursor_name
This is the name of an explicit cursor that is not currently open. For naming conventions, see “Identifiers” on page 2 – 4.

input_parameter
This is the name of a formal cursor parameter and is typically referenced in the WHERE clause. For naming conventions, see “Identifiers” on page 2 – 4. The syntax of parameter is the same as the syntax of plsql_expression, which is defined in “Expressions” on page 9 – 40.

If formal parameters are declared, actual parameters must be passed to the cursor. The values of actual parameters are used when the cursor is opened. The datatypes of the actual parameters must be compatible with the datatypes of the corresponding formal parameters. For more information, see “Datatypes” on page 2 – 10. In addition to the actual parameters, the query can reference PL/SQL variables defined within its scope.

Unless you want to accept default values, each formal parameter in the cursor declaration must have a corresponding actual parameter in the OPEN statement. Formal parameters declared with a default value need not have a corresponding actual parameter. They can simply assume their default values when the OPEN statement is executed.

The formal parameters of a cursor must be IN parameters. Therefore, they cannot return values to actual parameters.

You can associate the actual parameters in an OPEN statement with the formal parameters in a cursor declaration using positional or named notation. For more information, see “Positional and Named Notation” on page 6 – 12.
Usage Notes

Generally, PL/SQL parses an explicit cursor only the first time it is opened and parses a SQL statement (thereby creating an implicit cursor) only the first time the statement is executed.

All the parsed SQL statements are cached. A SQL statement must be reparsed only if it is bumped out of the cache by a new SQL statement.

So, although you must close a cursor before you can reopen it, PL/SQL need not reparse the associated SELECT statement. If you close, then immediately reopen the cursor, a reparse is definitely not needed.

Rows in the active set are not retrieved when the OPEN statement is executed. The FETCH statement retrieves the rows. With a FOR UPDATE cursor, the rows are locked when the cursor is opened.

If a cursor is currently open because you opened it, you cannot use the same cursor name in a cursor FOR loop.

Examples

Given the cursor declaration

```sql
CURSOR parts_cur IS SELECT part_num, part_price FROM parts;
```

the following statement opens the cursor:

```sql
OPEN parts_cur;
```

Given the cursor declaration

```sql
CURSOR emp_cur(my_ename CHAR, my_comm NUMBER DEFAULT 0)
  IS SELECT ...;
```

any of the following statements opens the cursor:

```sql
OPEN emp_cur('BLAKE', 300);
OPEN emp_cur(employee_name, 150);
OPEN emp_cur('TRUSDALE', my_comm);
OPEN emp_cur('LEE');
```

In the last example, the variable referenced in the OPEN statement has the same name as the formal parameter in the cursor declaration. When `my_comm` is used in the cursor declaration, it refers to the formal parameter `my_comm`. When it is used outside the declaration, it refers to the variable `my_comm`. For clarity, use unique identifiers.

CLOSE, Cursors, FETCH, LOOP
OPEN–FOR Statement

Description
The OPEN–FOR statement executes the multi–row query associated with a cursor variable. It also allocates resources used by Oracle to process the query and identifies the active set, which consists of all rows that meet the query search criteria. The cursor variable is positioned before the first row in the active set. For more information, see “Using Cursor Variables” on page 4–17.

Syntax
open_cursor_variable_statement ::=   

where cursor_variable stands for the following syntax:

variable_name   
:bind_variable_name   
parameter_name

Keyword and Parameter Description

select_statement  
This is a query associated with cursor_variable, which returns a set of values. The query can reference bind variables and PL/SQL variables, parameters, and functions but cannot be FOR UPDATE. The syntax of select_statement is similar to the syntax for select_into_statement defined in “SELECT INTO Statement” on page 9–107, except that select_statement cannot have an INTO clause.

variable_name  
This is the name of a cursor variable previously declared in a PL/SQL block or subprogram. For naming conventions, see “Identifiers” on page 2–4.

bind_variable_name  
This is the name of a cursor variable previously declared in a PL/SQL host environment and passed to PL/SQL as a bind variable. The datatype of the host cursor variable is compatible with the return type of any select_statement or PL/SQL cursor variable. Host variables must be prefixed with a colon. For more information, see “Host Objects” on page 9–43.

parameter_name  
This is the name of a cursor variable declared as the formal parameter of a PL/SQL subprogram. It should be declared as an IN OUT parameter so that the subprogram can return an open cursor to the caller. For naming conventions, see “Identifiers” on page 2–4.
Usage Notes

You must open a cursor variable on the server side. You do that by passing it as a bind variable to an anonymous PL/SQL block. At runtime, the block is sent to the Oracle Server for execution. Other OPEN–FOR statements can open the same cursor variable for different queries. You need not close a cursor variable before reopening it.

You can pass a cursor variable to PL/SQL by calling a stored procedure that declares a cursor variable as one of its formal parameters. Currently, however, remote subprograms cannot return the values of cursor variables. Therefore, you cannot use a remote procedure to open a cursor variable.

Examples

In the following Pro*C example, you pass a host cursor variable to a PL/SQL block, which opens the cursor variable:

```sql
EXEC SQL EXECUTE
   /* Pass cursor variable to PL/SQL block. */
   BEGIN
      /* Open cursor variable. */
      OPEN :emp_cur FOR SELECT * FROM emp;
      -- ^ bind variables must be prefixed with a colon
   END;
END-EXEC;
```

In the next Pro*C example, you pass a host cursor variable and a selector to an anonymous PL/SQL block that opens queries with different return types:

```sql
EXEC SQL EXECUTE
   /* Pass cursor variable and selector to PL/SQL block. */
   BEGIN
      IF :choice = 1 THEN
         OPEN :generic_cv FOR SELECT * FROM emp;
      ELSIF :choice = 2 THEN
         OPEN :generic_cv FOR SELECT * FROM dept;
      ELSIF :choice = 3 THEN
         OPEN :generic_cv FOR SELECT * FROM bonus;
      END IF;
   END;
END-EXEC;
```

Packages

Description
A package is a database object that groups logically related PL/SQL types, objects, and subprograms. Packages have two parts: a specification and a body. For more information, see Chapter 7.

Syntax

```
package_specification ::=  
   PACKAGE    package_name    IS  
      variable_declaration  
      constant_declaration  
      cursor_declaration  
      cursor_specification  
      exception_declaration  
      record_declaration  
      plsql_table_declaration  
      procedure_specification  
      function_specification  
   END  

package_body ::=  
   PACKAGE BODY    package_name    IS  
      variable_declaration  
      constant_declaration  
      cursor_declaration  
      cursor_body  
      exception_declaration  
      record_declaration  
      plsql_table_declaration  
      procedure_body  
      function_body  
   END  
```

</tr>
</tbody>
</table>
seq_of_statements

This represents a sequence of statements. For the syntax of *seq_of_statements*, see “Blocks” on page 9 – 10.

exception_handler

This construct associates an exception with a sequence of statements, which is executed when that exception is raised. For the syntax of *exception_handler*, see “Exceptions” on page 9 – 35.

Usage Notes

You cannot define packages in a PL/SQL block or subprogram. However, you can use any Oracle tool that supports PL/SQL to create and store packages in an Oracle database. You can issue the CREATE PACKAGE and CREATE PACKAGE BODY statements interactively from SQL*Plus or Server Manager and from an Oracle Precompiler or OCI host program. For the full syntax of the CREATE statement, see Oracle7 Server SQL Reference.

Most packages have a specification and a body. The specification is the interface to your applications; it declares the types, variables, constants, exceptions, cursors, and subprograms available for use. The body fully defines cursors and subprograms, and so implements the specification.

Only subprograms and cursors have an underlying implementation (definition). So, if a specification declares only types, constants, variables, and exceptions, the package body is unnecessary.

When designing an application, all you need initially is the interface information in the package specifications. You can code and compile a specification without its body. Once the specification has been compiled, stored subprograms that reference the package can be compiled as well. You need not define the package bodies fully until you are ready to complete the application.

Furthermore, you can debug, enhance, or replace a package body without changing the interface (package specification) to the package body. That means you need not recompile calling programs.

Cursors and subprograms declared in a package specification must be defined in the package body. Other program objects declared in the package specification cannot be redeclared in the package body.

To match subprogram specifications and bodies, PL/SQL does a token–by–token comparison of their headers. So, except for white space, the headers must match word for word. Otherwise, PL/SQL raises an exception.

Cursors, Exceptions, Functions, PL/SQL Tables, Procedures, Records
PL/SQL Tables

Description

PL/SQL tables are objects of type TABLE, which are modelled as (but not the same as) database tables. PL/SQL tables use a primary key to give you array–like access to rows. Like the size of a database table, the size of a PL/SQL table is unconstrained. That is, the number of rows in a PL/SQL table can increase dynamically. For more information, see “PL/SQL Tables” on page 2–38.

PL/SQL tables must be declared in two steps. First, you define a TABLE type, then declare PL/SQL tables of that type.

Syntax

```
plsql_table_declaration ::= plsql_table_type + plsql_table

plsql_table_type ::= INDEX BY BINARY_INTEGER

plsql_table ::= plsql_table_name plsql_table_type;
```

Keyword and Parameter Description

**type_name**

This is the name of a user–defined type specifier, which is used in subsequent declarations of PL/SQL tables. For naming conventions, see “Identifiers” on page 2–4.

**column_type**

This specifies the datatype of the column in a PL/SQL table. It can be any scalar (not composite) datatype. For more information, see “Datatypes” on page 2–10.

**table.column**

This refers to a table and column that must be accessible when the declaration is elaborated.
INDEX BY BINARY INTEGER

The primary key of a PL/SQL table must have datatype BINARY_INTEGER, which can represent signed integers of any practical size. The magnitude range of a BINARY_INTEGER value is $-2^{31} \ldots 2^{31}-1$.

plsql_table_name

The is the name of an entire PL/SQL table. For naming conventions, see “Identifiers” on page 2 – 4.

Usage Notes

You can declare TABLE types and PL/SQL tables in the declarative part of any block, subprogram, or package. PL/SQL tables can have one column and a primary key, neither of which can be named. The column can have any scalar datatype, but the primary key must have datatype BINARY_INTEGER. You can use the %TYPE attribute to specify a column datatype.

Unlike an array, a PL/SQL table is unconstrained (not of fixed size) because its primary key can assume any value in the range of values defined for BINARY_INTEGER. As a result, you cannot initialize a PL/SQL table in its declaration. For example, the following declaration is invalid:

```sql
job_tab  JobTabTyp := ('CLERK', 'ANALYST', 'MANAGER');
```

The first reference to a row in a PL/SQL table must be an assignment. Otherwise, the predefined exception NO_DATA_FOUND is raised.

PL/SQL tables follow the usual scoping and instantiation rules. In a package, they are instantiated when you first reference the package and cease to exist when you exit the application or end the database session. In a block or subprogram, they are instantiated when you enter the block or subprogram and cease to exist when you exit the block or subprogram.

Like scalar variables, PL/SQL tables can be declared as the formal parameters of procedures and functions. The restrictions that apply to scalar parameters also apply to PL/SQL tables.

Examples

In the following example, you declare a TABLE type named SalTabTyp:

```sql
DECLARE
    TYPE SalTabTyp IS TABLE OF NUMBER(7,2)
    INDEX BY BINARY_INTEGER;
```

You could have used %TYPE to provide the column datatype, as follows:

```sql
DECLARE
    TYPE SalTabTyp IS TABLE OF emp.sal%TYPE
    INDEX BY BINARY_INTEGER;
```
Once you define type `SalTabTyp`, you can declare PL/SQL tables of that type, as follows:

```plsql
sal_tab  SalTabTyp;
```

The identifier `sal_tab` represents an entire PL/SQL table.

In the following example, you assign the sum of variables `salary` and `increase` to the tenth row in PL/SQL table `sal_tab`:

```plsql
sal_tab(10) := salary * increase;
```

Assignment Statement, Functions, Procedures, Records
Procedures

Description

A procedure is a named PL/SQL block, which can take parameters and be invoked. Generally, you use a procedure to perform an action. For more information, see “Procedures” on page 6 – 3.

A procedure has two parts: the specification and the body. The procedure specification begins with the keyword PROCEDURE and ends with the procedure name or a parameter list. Parameter declarations are optional. Procedures that take no parameters are written without parentheses.

The procedure body begins with the keyword IS and ends with the keyword END followed by an optional procedure name. The procedure body has three parts: a declarative part, an executable part, and an optional exception–handling part.

The declarative part contains declarations of types, cursors, constants, variables, exceptions, and subprograms. These objects are local and cease to exist when you exit the procedure. The executable part contains statements that assign values, control execution, and manipulate Oracle data. The exception–handling part contains exception handlers, which deal with exceptions raised during execution.

Syntax

procedure_specification ::= 

PROCEDURE — procedure_name 

{ parameter } 

; 

procedure_specification ::= procedure_body

procedure_body ::= 

PROCEDURE — procedure_name 

{ parameter } 

IS 

;
This is the name of a procedure. For naming conventions, see “Identifiers” on page 2–4.

This construct declares a variable. For the syntax of variable_declaration, see “Variables and Constants” on page 9–120.

This construct declares a constant. For the syntax of constant_declaration, see “Variables and Constants” on page 9–120.
cursor_declaration  This construct declares an explicit cursor. For the syntax of
                    cursor_declaration, see “Cursors” on page 9 – 23.

cursor_variable_  This construct declares a cursor variable. For the syntax of
declaration       cursor_variable_declaration, see “Cursor Variables” on page 9 – 27.

exception_declaration  This construct declares an exception. For the syntax of
                       exception_declaration, see “Exceptions” on page 9 – 35.

record_declaration  This construct declares a user–defined record. For the syntax of
                    record_declaration, see “Records” on page 9 – 94.

plsql_table_declaration  This construct declares a PL/SQL table. For the syntax of
                        plsql_table_declaration, see “PL/SQL Tables” on page 9 – 85.

procedure_declaration  This construct declares a nested procedure.

function_declaration  This construct declares a function. For the syntax of function_declar,
                       see “Functions” on page 9 – 50.

seq_of_statements  This represents a sequence of statements. For the syntax of
                   seq_of_statements, see “Blocks” on page 9 – 10.

exception_handler  This construct associates an exception with a sequence of statements,
                   which is executed when that exception is raised. For the syntax of
                   exception_handler, see “Exceptions” on page 9 – 35.

parameter_name  This is the name of a formal parameter, which is a variable declared in a
                 procedure specification and referenced in the procedure body. For
                 naming conventions, see “Identifiers” on page 2 – 4.

IN, OUT, IN OUT  These parameter modes define the behavior of formal parameters. The
                 IN parameter mode lets you pass values to the subprogram being called. An OUT
                 parameter lets you return values to the caller of the subprogram. An IN OUT
                 parameter lets you pass initial values to the subprogram being called and return
                 updated values to the caller.

type_name  This specifies the datatype of a formal parameter. For more information,
            see “Datatypes” on page 2 – 10.

            Unlike the datatype specifier in a variable declaration, the datatype specifier in a parameter declaration must be unconstrained. For example, the following declaration of emp_name is illegal:

            PROCEDURE ... (emp_name CHAR(20)) IS -- illegal
            BEGIN ... END;

            ...
This refers to a database table and column that must be accessible when the declaration is elaborated.

This refers to a database table that must be accessible when the declaration is elaborated.

This attribute provides the datatype of a variable or database column.

This attribute provides a record that represents a row in a database table. Columns in a row and corresponding fields in a record have the same names and datatypes.

This is an arbitrarily complex expression, which is used to initialize a parameter. The syntax of `plsql_expression` is defined in “Expressions” on page 9 – 40. The value of `plsql_expression` is assigned to the parameter identified by `parameter_name`. The datatype of `plsql_expression` must be compatible with the datatype of the parameter. For more information, see “Datatype Conversion” on page 2 – 16.

At least one statement must appear in the executable part of a procedure. The NULL statement meets this requirement.

A procedure is called as a PL/SQL statement. For example, the procedure `raise_salary` might be called as follows:

```
raise_salary(emp_num, amount);
```

Inside a procedure, an IN parameter acts like a constant. Therefore, it cannot be assigned a value. An OUT parameter acts like an uninitialized variable. So, its value cannot be assigned to another variable or reassigned to itself. An IN OUT parameter acts like an initialized variable. Therefore, it can be assigned a value, and its value can be assigned to another variable. For summary information about the parameter modes, see Table 6–1 on page 6 – 15.

Before exiting a procedure, explicitly assign values to all OUT formal parameters. Otherwise, the values of corresponding actual parameters are indeterminate. If you exit successfully, PL/SQL assigns values to the actual parameters. However, if you exit with an unhandled exception, PL/SQL does not assign values to the actual parameters.

Unlike OUT and IN OUT parameters, IN parameters can be initialized to default values. For more information, see “Parameter Default Values” on page 6 – 15.
You can write the procedure specification and body as a unit. Or, you can separate the procedure specification from its body. That way, you can hide implementation details by placing the procedure in a package. You can define procedures in a package body without declaring their specifications in the package specification. However, such procedures can be called only from inside the package.

Procedures can be defined using any Oracle tool that supports PL/SQL. To become available for general use, however, procedures must be CREATEd and stored in an Oracle database. You can issue the CREATE PROCEDURE statement interactively from SQL*Plus or SQL*DBA. For the full syntax of the CREATE statement, see Oracle7 Server SQL Reference.

Example

The following procedure debits a bank account:

```plsql
PROCEDURE debit_account (acct_id INTEGER, amount REAL) IS
    old_balance  REAL;
    new_balance  REAL;
    overdrawn    EXCEPTION;
BEGIN
    SELECT bal INTO old_balance FROM accts WHERE acctno = acct_id;
    new_balance := old_balance – amount;
    IF new_balance < 0 THEN
        RAISE overdrawn;
    ELSE
        UPDATE accts SET bal = new_balance WHERE acctno = acct_id;
    END IF;
EXCEPTION
    WHEN overdrawn THEN
    ...
END debit_account;
```

In the following example, you call the procedure using named notation:

```plsql
debit_account(amount => 500, acct_id => 10261);
```

RAISE Statement

Description
The RAISE statement stops normal execution of a PL/SQL block or subprogram and transfers control to the appropriate exception handler. For more information, see “User–Defined Exceptions” on page 5–7.

Normally, predefined exceptions are raised implicitly by the runtime system. However, RAISE statements can also raise predefined exceptions. User–defined exceptions must be raised explicitly by RAISE statements.

Syntax
raise_statement ::= RAISE exception_name ;

Keyword and Parameter Description

exception_name
This is the name of a predefined or user–defined exception. For naming conventions, see “Identifiers” on page 2–4. For a list of the predefined exceptions, see “Predefined Exceptions” on page 5–5.

Usage Notes
PL/SQL blocks and subprograms should RAISE an exception only when an error makes it impractical or impossible to finish processing. You can code a RAISE statement for a given exception anywhere within the scope of that exception.

When an exception is raised, if PL/SQL cannot find a handler for it in the current block or subprogram, the exception propagates. That is, the exception reproduces itself in successive enclosing blocks until a handler is found or there are no more blocks to search. In the latter case, PL/SQL returns an unhandled exception error to the host environment.

Omitting the exception name in a RAISE statement—allowed only in an exception handler—reraises the current exception. When a parameterless RAISE statement executes in an exception handler, the first block searched is the enclosing block, not the current block.

Examples
As the following example shows, you can raise a predefined exception explicitly:

RAISE INVALID_NUMBER;

Related Topics
Exceptions
Records

Description
Records are objects of type RECORD. Records have uniquely named fields that can store data values of different types. For more information, see “User–Defined Records” on page 2–44.

Records must be declared in two steps. First, you define a RECORD type, then declare user–defined records of that type.

Syntax

record_declaration ::= record_type + record

record_type ::= TYPE type_name IS RECORD

{ field_declaration } ;

where field_declaration stands for the following syntax:

field_name datatype_name

variable%TYPE
record_variable%TYPE
plsql_table%TYPE
table.column%TYPE
table%ROWTYPE
cursor%ROWTYPE
cursor_variable%ROWTYPE

 NOT NULL := plsql_expression
DEFAULT

record ::= record_name record_type ;

Keyword and Parameter Description

type_name
This is the name of a user–defined type specifier, which is used in subsequent declarations of records. For naming conventions, see “Identifiers” on page 2–4.

field_name
This is the name of a field in a user–defined record. For naming conventions, see “Identifiers” on page 2–4.
field_type  This specifies the datatype of a field in a user–defined record. It can be any datatype including RECORD and TABLE. For more information, see “Datatypes” on page 2 – 10.

table   This refers to a table that must be accessible when the declaration is elaborated.

table.column  This refers to a table and column that must be accessible when the declaration is elaborated.

%TYPE  This attribute provides the datatype of a variable or database column.

%ROWTYPE  This attribute provides a record that represents a row in a database table. Columns in a row and corresponding fields in a record have the same names and datatypes.

NOT NULL  This constraint prevents the assigning of nulls to a field. At run time, trying to assign a null to a field defined as NOT NULL raises the predefined exception VALUE_ERROR. The constraint NOT NULL must be followed by an initialization clause.

plsql_expression  This is an arbitrarily complex expression, which is used to initialize a field. The syntax of plsql_expression is defined in “Expressions” on page 9 – 40. The value of plsql_expression is assigned to the field identified by field_name. The datatype of plsql_expression must be compatible with the datatype of the field. For more information, see “Datatype Conversion” on page 2 – 16.

record_name  This is the name of a user–defined record. For naming conventions, see “Identifiers” on page 2 – 4.

Usage Notes  You can declare RECORD types and user–defined records in the declarative part of any block, subprogram, or package. Furthermore, a record can be initialized in its declaration, as the following example shows:

    DECLARE
    TYPE TimeTyp IS RECORD(
        second SMALLINT := 0,
        minute SMALLINT := 0,
        hour   SMALLINT := 0);
    
    The next example shows that you can use the %TYPE attribute to specify a field datatype. It also shows that you can add the NOT NULL constraint to any field declaration and so prevent the assigning of nulls to that field.
DECLARE
    TYPE DeptRecTyp IS RECORD(
        deptno NUMBER(2) NOT NULL,
        dname dept.dname%TYPE,
        loc dept.loc%TYPE);
    dept_rec DeptRecTyp;

To reference individual fields in a record, you use dot notation. For example, you might assign a value to the dname field in the dept_rec record as follows:

depth_rec.dname := ‘PURCHASING’;

Instead of assigning values separately to each field in a record, you can assign values to all fields at once. This can be done in two ways. First, PL/SQL lets you assign one record to another if they have the same datatype. Note, however, that even if their fields match exactly, a user-defined record and a %ROWTYPE record have different types. Second, you can assign a list of column values to a record by using the SELECT or FETCH statement. Just make sure the column names appear in the same order as the fields in your record.

You can declare and reference nested records. That is, a record can be the component of another record, as the following example shows:

DECLARE
    TYPE TimeTyp IS RECORD(
        minute SMALLINT,
        hour SMALLINT);
    TYPE MeetingTyp IS RECORD(
        day DATE,
        time TimeTyp, -- nested record
        place CHAR(20),
        purpose CHAR(50));
    TYPE PartyTyp IS RECORD(
        day DATE,
        time TimeTyp, -- nested record
        loc CHAR(15));
    meeting MeetingTyp;
    seminar MeetingTyp;
    party PartyTyp;

The next example shows that you can assign one nested record to another if they have the same datatype:

seminar.time := meeting.time;
Such assignments are allowed even if the containing records have different datatypes as in

```sql
party.time := meeting.time;
```

User-defined records follow the usual scoping and instantiation rules. In a package, they are instantiated when you first reference the package and cease to exist when you exit the application or end the database session. In a block or subprogram, they are instantiated when you enter the block or subprogram and cease to exist when you exit the block or subprogram.

Like scalar variables, user-defined records can be declared as the formal parameters of procedures and functions. The restrictions that apply to scalar parameters also apply to user-defined records.

**Examples**

In the following example, you declare a RECORD type named `DeptRecTyp` and a record named `dept_rec`, then select a row of values into the record:

```sql
DECLARE
    TYPE DeptRecTyp IS RECORD(
        deptno NUMBER(2),
        dname  CHAR(14),
        loc    CHAR(13));
    dept_rec DeptRecTyp;
    ...
BEGIN
    SELECT deptno, dname, loc INTO dept_rec FROM dept
    WHERE deptno = 20;
    ...
END;
```

**Related Topics**

Assignment Statement, Functions, PL/SQL Tables, Procedures
RETURN Statement

Description
The RETURN statement immediately completes the execution of a subprogram and returns control to the caller. Execution then resumes with the statement following the subprogram call. In a function, the RETURN statement also sets the function identifier to the result value. For more information, see “RETURN Statement” on page 6 – 7.

Syntax
\[
\text{return\_statement ::= return} \quad \text{return \ \text{RETURN}} \quad \text{\{plsql\_expression\} \ ;}
\]

Keyword and Parameter Description

plsql_expression
This is an arbitrarily complex expression. It is evaluated when the RETURN statement is executed. The syntax of \text{plsql\_expression} is defined in “Expressions” on page 9 – 40. The value of \text{plsql\_expression} is assigned to a function identifier. The datatype of \text{plsql\_expression} must be compatible with the datatype specified in the RETURN clause of the function specification. For more information, see “Datatype Conversion” on page 2 – 16.

Usage Notes
Do not confuse the RETURN statement with the RETURN clause, which specifies the datatype of the result value in a function specification.

A subprogram can contain several RETURN statements, none of which need be the last lexical statement. Executing any of them completes the subprogram immediately. However, it is poor programming practice to have multiple exit points in a subprogram.

In procedures, a RETURN statement cannot contain an expression. The statement simply returns control to the caller before the normal end of the procedure is reached.

However, in functions, a RETURN statement must contain an expression, which is evaluated when the RETURN statement is executed. The resulting value is assigned to the function identifier. Therefore, a function must contain at least one RETURN statement. Otherwise, PL/SQL raises the predefined exception PROGRAM_ERROR at run time.
The RETURN statement can also be used in an anonymous block to exit the block (and all enclosing blocks) immediately, but the RETURN statement cannot contain an expression.

**Example**

In the following example, the function balance RETURNs the balance of a specified bank account:

```sql
FUNCTION balance (acct_id INTEGER) RETURN REAL IS
    acct_bal  REAL;
BEGIN
    SELECT bal INTO acct_bal FROM accts WHERE acctno = acct_id;
    RETURN acct_bal;
END balance;
```
ROLLBACK Statement

Description
The ROLLBACK statement is the inverse of the COMMIT statement. It undoes some or all database changes made during the current transaction. For more information, see “Processing Transactions” on page 4 – 35.

Syntax
```
rollback_statement ::=  
  ROLLBACK  WORK  
  TO  SAVEPOINT  savepoint_name  COMMENT 'text'

;  
```

Keyword and Parameter Description

ROLLBACK
When a parameterless ROLLBACK statement is executed, all database changes made during the current transaction are undone.

WORK
This keyword is optional and has no effect except to improve readability.

ROLLBACK TO savepoint_name
This statement undoes all database changes (and releases all locks acquired) since the savepoint identified by savepoint_name was marked. The identifier savepoint_name names a savepoint that was marked earlier in the current transaction using the SAVEPOINT statement. For naming conventions, see “Identifiers” on page 2 – 4.

SAVEPOINT
This keyword is optional and has no effect except to improve readability.

COMMENT
This keyword specifies a comment to be associated with the current transaction and is typically used with distributed transactions. The text must be a quoted literal up to 50 characters long.

Usage Notes
All savepoints marked after the savepoint to which you roll back are erased. However, the savepoint to which you roll back is not erased. For example, if you mark savepoints A, B, C, and D in that order, then roll back to savepoint B, only savepoints C and D are erased.
An implicit savepoint is marked before executing an INSERT, UPDATE, or DELETE statement. If the statement fails, a rollback to the implicit savepoint is done. Normally, just the failed SQL statement is rolled back, not the whole transaction. However, if the statement raises an unhandled exception, the host environment determines what is rolled back. For more information, see “Unhandled Exceptions” on page 5–20.

When a distributed transaction fails, the text specified by COMMENT helps you diagnose the problem. If a distributed transaction is ever in doubt, Oracle stores the text in the data dictionary along with the transaction ID. For more information about distributed transactions, see Oracle7 Server Concepts.

COMMIT, SAVEPOINT
%ROWCOUNT Attribute

Description
PL/SQL cursors and cursor variables have four attributes, including %ROWCOUNT, that give you useful information about the execution of a data manipulation statement. For more information, see “Using Cursor Attributes” on page 4–29.

There are two kinds of cursors: implicit and explicit. PL/SQL implicitly declares a cursor for all SQL data manipulation statements, including single-row queries. Until the SQL statement is executed, %ROWCOUNT yields a null. Thereafter, %ROWCOUNT yields the number of rows affected by an INSERT, UPDATE, or DELETE statement or returned by a SELECT INTO statement. %ROWCOUNT yields 0 if an INSERT, UPDATE, or DELETE statement affected no rows, or a SELECT INTO statement returned no rows.

For multi-row queries, you can explicitly declare a cursor or cursor variable to process the rows. When you open the cursor or cursor variable, %ROWCOUNT is zeroed. Before the first fetch, %ROWCOUNT yields 0. Thereafter, it yields the number of rows fetched so far. The number is incremented if the latest fetch returned a row.

Syntax

```
rowcount_attribute ::=  
  cursor_name  cursor_variable_name %ROWCOUNT
```

Keyword and Parameter Description

cursor_name
This is the name of an explicit cursor or the implicit SQL cursor. For naming conventions, see “Identifiers” on page 2–4.

cursor_variable_name
This is the name of a PL/SQL cursor variable. The cursor variable name follows the usual scoping rules.

Usage Notes
You can use the %ROWCOUNT attribute in procedural statements but not in SQL statements. %ROWCOUNT is associated with every cursor or cursor variable. So, you can open multiple cursors or cursor variables, then use %ROWCOUNT to tell how many rows have been fetched so far. If a cursor or cursor variable is not open, referencing it with %ROWCOUNT raises INVALID_CURSOR.

If a SELECT INTO statement returns more than one row, PL/SQL raises the predefined exception TOO_MANY_ROWS and sets %ROWCOUNT to 1, not the actual number of rows that satisfy the query.
Examples

The block in the following example returns the name, employee number, and salary of the five highest-paid employees:

```sql
-- available online in file EXAMP14
DECLARE
  CURSOR c1 is
    SELECT ename, empno, sal FROM emp
    ORDER BY sal DESC; -- start with highest-paid employee
  my_ename  CHAR(10);
  my_empno  NUMBER(4);
  my_sal    NUMBER(7,2);
BEGIN
  OPEN c1;
  LOOP
    FETCH c1 INTO my_ename, my_empno, my_sal;
    EXIT WHEN (c1%ROWCOUNT > 5) OR (c1%NOTFOUND);
    INSERT INTO temp VALUES (my_sal, my_empno, my_ename);
    COMMIT;
  END LOOP;
  CLOSE c1;
END;
```

In the next example, %ROWCOUNT is used to raise an exception if an unexpectedly high number of rows is deleted:

```sql
DELETE FROM accts WHERE status = ‘BAD DEBT’;
IF SQL%ROWCOUNT > 10 THEN
  RAISE out_of_bounds;
END IF;
```

CLOSE, Cursors, Cursor Variables, FETCH, INSERT, OPEN, SELECT INTO, UPDATE
%ROWTYPE Attribute

Description
The %ROWTYPE attribute provides a record that represents a row in a table (or view). The record can store an entire row of data selected from the table, or fetched from a cursor or cursor variable. Columns in a row and corresponding fields in a record have the same names and datatypes.

You use the %ROWTYPE attribute in variable declarations as a datatype specifier. Variables declared using %ROWTYPE are treated like those declared using a datatype name. For more information, see “Using %ROWTYPE” on page 2 – 20.

Syntax
rowtype_attribute ::=  
cursor_name %ROWTYPE 
cursor_variable_name 
table_name

Keyword and Parameter Description

cursor_name
This is the name of a previously declared cursor. The cursor name follows the usual scope rules. For naming conventions, see “Identifiers” on page 2 – 4.

cursor_variable_name
This is the name of a previously declared PL/SQL cursor variable. The cursor variable name follows the usual scoping rules.

table_name
This is the name of a database table (or view). You can precede the table name with an owner name, as in

    scott.dept

The table must be accessible when the declaration is elaborated.

Usage Notes
The %ROWTYPE attribute lets you declare records structured like a row of data in a database table. In the following example, you declare a record that can store an entire row from the emp table:

    emp_rec emp%ROWTYPE;

The column values returned by the SELECT statement are stored in fields. To reference a field, you use dot notation. For example, you might reference the deptno field as follows:

    IF emp_rec.deptno = 20 THEN ...
In addition, you can assign the value of an expression to a specific field, as the following example shows:

```sql
emp_rec.sal := average * 1.15;
```

There are two ways to assign values to all fields in a record at once. First, PL/SQL allows aggregate assignment between entire records if their declarations refer to the same table or cursor. Second, you can assign a list of column values to a record by using the SELECT or FETCH statement. The column names must appear in the order in which they were defined by the CREATE TABLE or CREATE VIEW statement. Select–items fetched from a cursor associated with %ROWTYPE must have simple names or, if they are expressions, must have aliases.

### Examples

In the example below, you use %ROWTYPE to declare two records. The first record stores a row selected from the `emp` table. The second record stores a row fetched from the `c1` cursor.

```sql
DECLARE
  emp_rec   emp%ROWTYPE;
  CURSOR c1 IS SELECT deptno, dname, loc FROM dept;
  dept_rec  c1%ROWTYPE;
END;
```

In the next example, you select a row from the `emp` table into a %ROWTYPE record:

```sql
DECLARE
  emp_rec   emp%ROWTYPE;
  ...
BEGIN
  SELECT * INTO emp_rec FROM emp WHERE empno = my_empno;
  IF (emp_rec.deptno = 20) AND (emp_rec.sal > 2000) THEN
    ...
  END IF;
END;
```

SAVEPOINT Statement

Description

The SAVEPOINT statement names and marks the current point in the processing of a transaction. With the ROLLBACK TO statement, savepoints let you undo parts of a transaction instead of the whole transaction. For more information, see “Processing Transactions” on page 4 – 35.

Syntax

savepoint_statement ::=  

SAVEPOINT savepoint_name ;

Keyword and Parameter Description

savepoint_name

This is an undeclared identifier, which names the current point in the processing of a transaction. For naming conventions, see “Identifiers” on page 2 – 4.

Usage Notes

When you roll back to a savepoint, any savepoints marked after that savepoint are erased. However, the savepoint to which you roll back is not erased. A simple rollback or commit erases all savepoints.

If you mark a savepoint within a recursive subprogram, new instances of the SAVEPOINT statement are executed at each level in the recursive descent. However, you can only roll back to the most recently marked savepoint.

Savepoint names can be reused within a transaction. This moves the savepoint from its old position to the current point in the transaction.

An implicit savepoint is marked before executing an INSERT, UPDATE, or DELETE statement. If the statement fails, a rollback to the implicit savepoint is done. Normally, just the failed SQL statement is rolled back, not the whole transaction. However, if the statement raises an unhandled exception, the host environment determines what is rolled back. For more information, see “Unhandled Exceptions” on page 5 – 20.

By default, the number of active savepoints per user process is limited to 5. You or your DBA can raise the limit (up to 255) by increasing the value of the Oracle initialization parameter SAVEPOINTS.

Related Topics

COMMIT, ROLLBACK
SELECT INTO Statement

Description

The SELECT INTO statement retrieves data from one or more database tables, then assigns the selected values to variables. For a full description of the SELECT statement, see Oracle7 Server SQL Reference.

Syntax

```plaintext
select_into_statement ::= 

SELECT select_list_item 

INTO variable_name FROM table_reference 

; 
```

where `table_reference` stands for the following syntax:

```plaintext

SELECT list alias 

INTO variable_name FROM table_reference 

; 
```

Keyword and Parameter Description

`select_list_item` This parameter retrieves a value for each `select_list_item` in the select list, then assigns the values to corresponding variables in the `variable_name` list or to corresponding fields in `record_name`.

`INTO variable_name` This parameter defines which scalar variables will store the retrieved data. All variables in the `variable_name` list must be previously declared.

For each `select_list_item` in the select list, there must be a corresponding variable in the `variable_name` list. Also, the datatype of the value returned by each `select_list_item` must be compatible with the datatype of each corresponding variable. For more information, see “Datatype Conversion” on page 2 – 16.
INTO record_name  
This parameter indicates that retrieved data is stored in a record variable declared using the %ROWTYPE attribute. An example follows:

```sql
DECLARE
    dept_rec  dept%ROWTYPE;
...
BEGIN
    SELECT deptno, dname, loc INTO dept_rec FROM dept
    WHERE deptno = 20;
...
END;
```

You use dot notation to access field values, as the following example shows:

```sql
dept_rec.deptno
```

table_reference  
The table or view specified by table_reference must be accessible when you execute the SELECT statement.

alias  
This is another (usually short) name for the referenced column, table, or view, and can be used in the WHERE clause.

rest_of_select_statement  
This parameter is anything that can legally follow the FROM clause in a SELECT statement.

Usage Notes  
The implicit SQL cursor and the cursor attributes %NOTFOUND, %FOUND, %ROWCOUNT, and %ISOPEN let you access useful information about the execution of a SELECT INTO statement. For more information, see “Managing Cursors” on page 4 – 10.

When you use a SELECT INTO statement to assign values to variables, it must return only one row from the table. If more than one row is returned, you get the following results:

- PL/SQL raises the predefined exception TOO_MANY_ROWS
- SQLCODE returns −1422 (Oracle error code ORA–01422)
- SQLERRM returns the Oracle error message single-row query returns more than one row
- SQL%NOTFOUND yields FALSE
- SQL%FOUND yields TRUE
- SQL%ROWCOUNT yields 1
If no rows are returned, you get the following results:

- PL/SQL raises the predefined exception NO_DATA_FOUND unless the SELECT statement called a SQL group function such as AVG or SUM. (SQL group functions always return a value or a null. So, a SELECT INTO statement that calls a group function never raises NO_DATA_FOUND.)
- SQLCODE returns +100 (Oracle error code ORA–01403)
- SQLERRM returns the Oracle error message *no data found*
- SQL%NOTFOUND yields TRUE
- SQL%FOUND yields FALSE
- SQL%ROWCOUNT yields 0

**Example**

```sql
SELECT ename, job, sal*1.1 INTO my_ename, my_job, wages FROM emp
WHERE empno = my_empno;
```

**Related Topics**

Assignment Statement, FETCH, %ROWTYPE
SET TRANSACTION Statement

Description
The SET TRANSACTION statement establishes a read-only or read-write transaction or assigns your current transaction to a specified rollback segment. For more information, see “Using SET TRANSACTION” on page 4-40.

Syntax
```
set_transaction_statement ::=  
  SET TRANSACTION  [READ ONLY]  
  [READ WRITE]  
  USE ROLLBACK SEGMENT segment_name
```

Keyword and Parameter Description

READ ONLY
This clause establishes the current transaction as read-only. If a transaction is set to READ ONLY, subsequent queries see only changes committed before the transaction began. The use of READ ONLY does not affect other users or transactions.

READ WRITE
This clause establishes the current transaction as read-write. The use of READ WRITE does not affect other users or transactions. If you issue a data manipulation statement in your transaction, Oracle assigns the transaction to a rollback segment.

USE ROLLBACK SEGMENT
This clause assigns the current transaction to the specified rollback segment and establishes the transaction as read-write. You cannot use this parameter with the READ ONLY parameter in the same transaction because read-only transactions do not generate rollback information.

Usage Notes
The SET TRANSACTION statement must be the first SQL statement in your transaction and can appear only once in the transaction. Only the SELECT INTO, OPEN, FETCH, CLOSE, LOCK TABLE, COMMIT, and ROLLBACK statements are allowed in a read-only transaction. For example, including an INSERT statement raises an exception. Also, queries cannot be FOR UPDATE.

Example
```
  COMMIT;  -- end previous transaction
  SET TRANSACTION READ ONLY;
  SELECT ... FROM emp WHERE ...  
  SELECT ... FROM dept WHERE ...  
  SELECT ... FROM emp WHERE ...  
  COMMIT;  -- end read-only transaction
```

Related Topics
COMMIT, ROLLBACK, SAVEPOINT
SQL Cursor

Description
Oracle implicitly opens a cursor to process each SQL statement not associated with an explicit cursor. PL/SQL lets you refer to the most recent implicit cursor as the “SQL” cursor. The SQL cursor has four attributes: %FOUND, %NOTFOUND, %ISOPEN, and %ROWCOUNT. They give you useful information about the execution of INSERT, UPDATE, DELETE, and SELECT INTO statements. For more information, see “Managing Cursors” on page 4 – 10.

Syntax

```
sql_cursor ::= SQL %FOUND %NOTFOUND %ISOPEN %ROWCOUNT
```

Keyword and Parameter Description

- **%FOUND**
  This attribute yields TRUE if an INSERT, UPDATE, or DELETE statement affected one or more rows or a SELECT INTO statement returned one or more rows. Otherwise, it yields FALSE.

- **%NOTFOUND**
  This attribute is the logical opposite of %FOUND. %NOTFOUND yields TRUE if an INSERT, UPDATE, or DELETE statement affected no rows, or a SELECT INTO statement returned no rows. Otherwise, %NOTFOUND yields FALSE.

- **%ISOPEN**
  This attribute always yields FALSE because Oracle closes the SQL cursor automatically after executing its associated SQL statement.

- **%ROWCOUNT**
  This attribute yields the number of rows affected by an INSERT, UPDATE, or DELETE statement, or returned by a SELECT INTO statement.

Usage Notes
You can use cursor attributes in procedural statements but not in SQL statements. Before Oracle opens the SQL cursor automatically, the implicit cursor attributes yield NULL.

The values of cursor attributes always refer to the most recently executed SQL statement, wherever that statement appears. It might be in a different scope. So, if you want to save an attribute value for later use, assign it to a Boolean variable immediately.
If a SELECT INTO statement fails to return a row, PL/SQL raises the predefined exception NO_DATA_FOUND whether you check %NOTFOUND on the next line or not.

However, a SELECT INTO statement that calls a SQL group function never raises NO_DATA_FOUND. That is because group functions such as AVG and SUM always return a value or a null. In such cases, %NOTFOUND yields FALSE.

**Examples**

In the following example, %NOTFOUND is used to insert a row if an update affects no rows:

```sql
UPDATE emp SET sal = sal * 1.05 WHERE empno = my_empno;
IF SQL%NOTFOUND THEN
   INSERT INTO emp VALUES (my_empno, my_ename, ...);
END IF;
```

In the next example, you use %ROWCOUNT to act if more than 100 rows are deleted:

```sql
DELETE FROM parts WHERE status = 'OBSOLETE';
IF SQL%ROWCOUNT > 100 THEN
   ... -- more than 100 rows were deleted
END IF;
```

**Related Topics**

%FOUND, %NOTFOUND, %ISOPEN, %ROWCOUNT
SQLCODE Function

Description
The function SQLCODE returns the number code associated with the most recently raised exception. SQLCODE is meaningful only in an exception handler. Outside a handler, SQLCODE always returns zero.

For internal exceptions, SQLCODE returns the number of the associated Oracle error. The number that SQLCODE returns is negative unless the Oracle error is no data found, in which case SQLCODE returns +100. For user-defined exceptions, SQLCODE returns +1 unless you used the pragma EXCEPTION_INIT to associate the exception with an Oracle error number, in which case SQLCODE returns that error number. For more information, see “Using SQLCODE and SQLERRM” on page 5–18.

Syntax
sqlcode_function ::= SQLCODE

Usage Notes
You cannot use SQLCODE directly in a SQL statement. For example, the following statement is illegal:
INSERT INTO errors VALUES (SQLCODE, ...);

Instead, you must assign the value of SQLCODE to a local variable, then use the variable in the SQL statement, as follows:
DECLARE
  my_sqlcode  NUMBER;
BEGIN
  ...
  EXCEPTION
  ...
  WHEN OTHERS THEN
    my_sqlcode := SQLCODE;
    INSERT INTO errors VALUES (my_sqlcode, ...);
END;

SQLCODE is especially useful in the OTHERS exception handler because it lets you identify which internal exception was raised.

Related Topics Exceptions, SQLERRM
SQLERRM Function

**Description**

The function SQLERRM returns the error message associated with its error-number argument or, if the argument is omitted, with the current value of SQLCODE. SQLERRM with no argument is meaningful only in an exception handler. Outside a handler, SQLERRM with no argument always returns the following message:

ORA-0000: normal, successful completion

For internal exceptions, SQLERRM returns the message associated with the Oracle error that occurred. The message begins with the Oracle error code.

For user-defined exceptions, SQLERRM returns the message User-Defined Exception unless you used the pragma EXCEPTION_INIT to associate the exception with an Oracle error number, in which case SQLERRM returns the corresponding error message. For more information, see “Using SQLCODE and SQLERRM” on page 5–18.

**Syntax**

```
sqlerrm_function ::= SQLERRM { error_number }
```

**Keyword and Parameter Description**

error_number

This argument must be a valid Oracle error number. For a list of Oracle errors, see Oracle7 Server Messages.

**Usage Notes**

You can pass an error number to SQLERRM, in which case SQLERRM returns the message associated with that error number. The error number passed to SQLERRM should be negative. Passing a zero to SQLERRM always returns the following message:

ORA-0000: normal, successful completion

Passing a positive number to SQLERRM always returns the message User-Defined Exception unless you pass +100, in which case SQLERRM returns the following message:

ORA-01403: no data found
You cannot use SQLERRM directly in a SQL statement. For example, the following statement is illegal:

```
INSERT INTO errors VALUES (SQLERRM, ...);
```

Instead, you must assign the value of SQLERRM to a local variable, then use the variable in the SQL statement, as follows:

```sql
DECLARE
  my_sqlerrm  CHAR(150);
...
BEGIN
  ...
EXCEPTION
  ...
    WHEN OTHERS THEN
  my_sqlerrm := SUBSTR(SQLERRM, 1, 150);
  INSERT INTO errors VALUES (my_sqlerrm, ...);
END;
```

The string function SUBSTR ensures that a VALUE_ERROR exception (for truncation) is not raised when you assign the value of SQLERRM to `my_sqlerrm`. SQLERRM is especially useful in the OTHERS exception handler because it lets you identify which internal exception was raised.

**Related Topics**  
Exceptions, SQLCODE
%TYPE Attribute

Description
The %TYPE attribute provides the datatype of a variable, record variable, field, PL/SQL table, or database column. You can use the %TYPE attribute as a datatype specifier when declaring constants, variables, fields, and parameters. For more information, see “Using %TYPE” on page 2–19.

Syntax
```
variable %TYPE
record_variable
field
plsql_table
table.column
```

Keyword and Parameter Description

**variable**
This is the name of a variable previously declared in the same scope. For naming conventions, see “Identifiers” on page 2–4.

**record_variable**
This is the name of a record variable previously declared (using %ROWTYPE, for example) in the same scope.

**field**
This is the name of a field previously declared in the same user-defined record.

**variable**
This is the name of a PL/SQL table previously declared in the same scope.

**table.column**
This refers to a table and column that must be accessible when the declaration is elaborated.

Usage Notes
The %TYPE attribute is particularly useful when declaring variables, fields, and parameters that refer to database columns. You can reference a table and column or you can reference an owner, table, and column. Also, a %TYPE declaration can include an initialization clause, as the following example shows:

```
my_comm scott.emp.comm%TYPE DEFAULT 0.0;
```

However, the NOT NULL column constraint does not apply to variables, fields, and parameters declared using %TYPE.

Related Topics
%ROWTYPE, Variables and Constants
UPDATE Statement

Description

The UPDATE statement changes the values of specified columns in one or more rows in a table or view. For a full description of the UPDATE statement, see Oracle7 Server SQL Reference.

Syntax

update_statement ::= 

   UPDATE table_reference 

   SET column_name = sql_expression 

   {column_name} = (select_statement) 

   WHERE search_condition 

   CURRENT OF cursor_name 

   ;

where table_reference stands for the following syntax:

   schema. view @dblink

Keyword and Parameter Description

table_reference

This specifies a table or view, which must be accessible when you execute the UPDATE statement, and for which you must have UPDATE privileges.

alias

This is another (usually short) name for the referenced table or view and is typically used in the WHERE clause.

column_name

This is the name of the column (or one of the columns) to be updated. It must be the name of a column in the referenced table or view. The column names must not be repeated in the column_name list. They need not appear in the UPDATE statement in the same order that they appear in the table or view.

SET column_name = sql_expression

This clause assigns the value of the sql_expression to the column called column_name. The term sql_expression can be any valid SQL expression. If sql_expression contains references to columns in the table being updated, the references are resolved in the context of the current row. The old column values are used on the right side of the equal sign.
In the following example, you increase every employee’s salary by 10%. The original value of the `sal` column is multiplied by 1.1, then the result is assigned to the `sal` column.

```
UPDATE emp SET sal = sal * 1.1;
```

<table>
<thead>
<tr>
<th>Clause Description</th>
<th>Code Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET column_name = one_val_sel_stmt</code></td>
<td>This clause assigns the value retrieved from the database by the <code>one_val_sel_stmt</code> to the sole column in the <code>column_name</code> list.</td>
</tr>
<tr>
<td><code>SET (column_name) = select_statement</code></td>
<td>This clause assigns the values retrieved from the database by <code>select_statement</code> to the columns listed in the <code>column_name</code> list.</td>
</tr>
<tr>
<td><code>WHERE search_condition</code></td>
<td>This clause conditionally chooses the rows in <code>table_reference</code> to be updated. Only rows that meet the <code>search_condition</code> are updated. If you omit <code>search_condition</code>, all rows in the table are updated.</td>
</tr>
</tbody>
</table>

The syntax of `one_val_sel_stmt` is similar to the syntax for `select_into_statement` defined in “SELECT INTO Statement” on page 9 – 107, except that it cannot have an INTO clause and must return exactly one row and one column.

The syntax of `select_statement` is similar to the syntax for `select_into_statement` defined in “SELECT INTO Statement” on page 9 – 107, except that it cannot have an INTO clause.

The column values returned by `select_statement` are assigned to the columns in the `column_name` list in order. Thus, the first column value returned by `select_statement` is assigned to the first column in the `column_name` list, the second column value is assigned to the second column in the `column_name` list, and so on.

In the following correlated query, `item_id` is assigned the value stored in the `item_id_num` column and `price` is assigned the value stored in the `item_price` column:

```
UPDATE inventory inv  -- alias
    SET (item_id, price) = (SELECT item_id_num, item_price
                        FROM item_table
                        WHERE item_name = inv.item_name);
```

If you omit `search_condition`, all rows in the table are updated.
WHERE CURRENT OF cursor_name

This clause refers to the latest row processed by the FETCH statement associated with cursor_name. The named cursor must have been declared using the FOR UPDATE clause and must be open and positioned on a row. If the cursor is not open, using the CURRENT OF clause results in an error. If the cursor is open, but no rows have been fetched or the last fetch returned no rows, PL/SQL raises the predefined exception NO_DATA_FOUND.

Usage Notes

The UPDATE WHERE CURRENT OF statement can be used after a fetch from an open cursor, provided the associated query was declared with a FOR UPDATE clause. The UPDATE WHERE CURRENT OF statement updates the current row.

The implicit SQL cursor and the cursor attributes %NOTFOUND, %FOUND, %ROWCOUNT, and %ISOPEN let you access useful information about the execution of an UPDATE statement. For more information, see “Managing Cursors” on page 4 – 10.

An UPDATE statement might update one or more rows or it might update no rows. If one or more rows are updated, you get the following results:

- SQL%NOTFOUND yields FALSE
- SQL%FOUND yields TRUE
- SQL%ROWCOUNT yields the number of rows updated

If no rows are updated, you get the following results:

- SQL%NOTFOUND yields TRUE
- SQL%FOUND yields FALSE
- SQL%ROWCOUNT yields 0

Examples

In the following example, a 10% raise is given to all analysts and clerks in department 20:

```
UPDATE emp SET sal = sal * 1.10
    WHERE (job = 'ANALYST' OR job = 'CLERK') AND DEPTNO = 20;
```

In the next example, Ford’s job is changed and her salary raised by 15%:

```
UPDATE emp SET job = 'ANALYST', sal = sal * 1.15
    WHERE ename = 'FORD';
```
Variables and Constants

Description
You can declare variables and constants in the declarative part of any PL/SQL block, subprogram, or package. Declarations allocate storage space for a value, specify its datatype, and name the storage location so that you can reference it. Declarations can also assign an initial value and impose the NOT NULL constraint. For more information, see “Declarations” on page 2–18.

Syntax

```
variable_declaration ::= 
  variable_name   datatype_name
  variable%TYPE
  record_variable%TYPE
  plsql_table%TYPE
  table.column%TYPE
  table%ROWTYPE
  cursor%ROWTYPE
  cursor_variable%ROWTYPE
  :
  plsql_expression ;
```

```
constant_declaration ::= 
  constant_name   CONSTANT datatype_name
  variable%TYPE
  record_variable%TYPE
  table.column%TYPE
  table%ROWTYPE
  cursor%ROWTYPE
  cursor_variable%ROWTYPE
  :
  plsql_expression ;
```

Keyword and Parameter Description

variable_name
This is the name of a program variable. For naming conventions, see “Identifiers” on page 2–4.

constant_name
This is the name of a program constant. For naming conventions, see “Identifiers” on page 2–4.

CONSTANT
This keyword denotes the declaration of a constant. You must initialize a constant in its declaration using a `plsql_expression`. Once initialized, the value of a constant cannot be changed.
This specifies the datatype of a variable or constant. For more information, see “Datatypes” on page 2 – 10.

This refers to a database table and column that must be accessible when the declaration is elaborated.

This refers to a database table that must be accessible when the declaration is elaborated.

This attribute provides the datatype of a variable or database column.

This attribute provides a record that represents a row in a database table. Columns in a row and corresponding fields in a record have the same names and datatypes.

This constraint prevents the assigning of nulls to a variable or constant. At run time, trying to assign a null to a variable defined as NOT NULL raises the predefined exception VALUE_ERROR. The constraint NOT NULL must be followed by an initialization clause.

This is an arbitrarily complex expression, which is used to initialize a variable or constant. The syntax of *plsql_expression* is defined in “Expressions” on page 9 – 40. The value of *plsql_expression* is assigned to the variable or constant identified by *variable_name* or *constant_name*, respectively. The datatype of *plsql_expression* must be compatible with the datatype of the variable or constant. For more information, see “Datatype Conversion” on page 2 – 16.

Variables and constants are initialized every time a block or subprogram is entered. By default, variables are initialized to NULL. So, unless you expressly initialize a variable, its value is undefined.

Whether public or private, variables and constants declared in a package specification are initialized only once per session.

A *plsql_expression* is required when declaring NOT NULL variables and when declaring constants. If a *plsql_expression* is not included in a variable declaration, the variable is assigned a null by default.

You cannot use the %ROWTYPE attribute to declare a constant. If %ROWTYPE is used, initialization is not allowed.
Examples

Several examples of variable and constant declarations follow:

invalid BOOLEAN := FALSE;
acct_id INTEGER(4) NOT NULL := 9999;
last_name VARCHAR2(20);
my_ename emp.ename%TYPE;
pi CONSTANT REAL := 3.14159;

Related Topics
Assignment Statement, Expressions, %ROWTYPE, %TYPE
This appendix surveys the new features in releases 2.1 and 2.2 of PL/SQL. Designed to meet your practical needs, these features will help you deliver effective, reliable applications.
Cursor Variables

Cursors differ from cursor variables the way constants differ from variables. While a cursor is static, a cursor variable is dynamic because it is not tied to a specific query. You can open a cursor variable for any type–compatible query. This gives you more flexibility.

Also, you can assign new values to a cursor variable and pass it as a parameter to subprograms, including subprograms stored in an Oracle database. This gives you a convenient way to centralize data retrieval. For more information, see page 4 – 17.

RESTRICT_REFERENCES Pragma

With earlier releases of PL/SQL, calls to stored functions could appear only in procedural statements, but now they can appear in SQL statements as well. That means you can use stored functions as if they were built–in SQL functions such as ROUND, LENGTH, and MONTHS_BETWEEN. For example, you might define a function named miles_between that returns the distance between two cities, then use the function in the WHERE clause of a SELECT statement to find employees who live within a given distance from company headquarters.

By extending SQL in this way, you can do complex data analysis within the Oracle Server; you need not retrieve the data into your application. This increases data independence.

However, to be callable from SQL expressions, a stored function must obey certain rules meant to control side effects. For standalone functions, Oracle can enforce these rules by checking the function body. However, the body of a packaged function is hidden. So, for packaged functions, you must use the pragma RESTRICT_REFERENCES to enforce the rules. For more information, see “Calling Stored Functions from SQL Expressions” in Oracle7 Server Application Developer’s Guide.
User-Defined Subtypes

A subtype does not introduce a new datatype; it merely places an optional constraint on its base type. For example, the predefined subtype CHARACTER is an unconstrained subtype because it specifies the same set of values as its base type, CHAR.

PL/SQL lets you define your own subtypes, which can increase reliability, provide compatibility with ANSI/ISO and IBM types, and improve readability. For more information, see page 2–49.

SQL92 Compliance

The current ANSI/ISO SQL standard, known informally as SQL92, specifies a “conforming SQL language” and defines three language levels: Full SQL, Intermediate SQL, and Entry SQL. A conforming SQL implementation must support at least Entry SQL.

PL/SQL achieves full support for Entry SQL by letting you

- reference column aliases in the ORDER BY clause
- use the keyword AS to introduce aliases in the SELECT clause

For more information, see page 4–7.

The PL/SQL Wrapper

The PL/SQL Wrapper is a standalone utility that converts PL/SQL source code into portable object code. You can use the Wrapper to deliver PL/SQL applications without exposing your source code.

By hiding application internals, the PL/SQL Wrapper prevents misuse of your application by other developers and exposure of your algorithms to business competitors. Wrapped code is as portable as source code, and the PL/SQL compiler recognizes and loads wrapped compilation units automatically. For more information, see Appendix D.
This appendix provides several PL/SQL programs to guide you in writing your own. The sample programs illustrate the following important PL/SQL concepts and features:

- FOR loops
- cursors
- scoping
- batch transaction processing
- embedded PL/SQL
- calling a stored procedure
Running the Samples

The sample programs in this appendix and many others throughout this Guide are available online. Therefore, they are preceded by the following comment:

-- available online in file <filename>

The list below gives their locations in this Guide and the names of the corresponding online files. However, the exact name and storage location of an online file are system dependent.

Some samples are run interactively from SQL*Plus; others are run from Pro*C programs. You can experiment with the samples from any Oracle account. However, the Pro*C examples expect you to use the SCOTT/TIGER account.

Before trying the samples, you must create some database tables, then load the tables with data. You do that by running two SQL*Plus scripts, EXAMPBLD and EXAMPLOD, supplied with PL/SQL. These scripts can be found in the PL/SQL installation library. Check the Oracle installation or user’s guide for your system.

Creating the Tables

Below is a listing of the SQL*Plus script EXAMPBLD. The CREATE statements in this script build the database tables processed by the sample programs. To run the script, invoke SQL*Plus, then issue the following command:

```sql
SQL> START EXAMPBLD
```

EXAMPBLD Script

```sql
set compatibility V6
/
drop table accounts
/
create table accounts(
    account_id  number(4) not null,
    bal         number(11,2))
/
create unique index accounts_index on accounts (account_id)
/
drop table action
/
create table action(
    account_id  number(4) not null,
    oper_type   char(1) not null,
    new_value   number(11,2),
    status      char(45),
    time_tag    date not null)
/
drop table bins
/
create table bins(
    bin_num     number(2) not null,
    part_num    number(4),
    amt_in_bin  number(4))
/
drop table data_table
/
```
create table data_table(
exper_num  number(2),
n1         number(5),
n2         number(5),
n3         number(5))
/
drop table emp
/
create table emp(
    empno      number(4) not null,
    ename      char(10),
    job        char(9),
    mgr        number(4),
    hiredate   date,
    sal        number(7,2),
    comm       number(7,2),
    deptno     number(2))
/
drop table inventory
/
create table inventory(
    prod_id     number(5) not null,
    product     char(15),
    quantity    number(5))
/

    end loop;
end get_employees;
end personnel;
/
Loading the Data

Below is a listing of the SQL*Plus script EXAMPLOD. The INSERT statements in this script load (or reload) the database tables processed by the sample programs. To run the script, invoke SQL*Plus in the same Oracle account from which you ran EXAMPBLD, then issue the following command:

```
SQL> START EXAMPLOD
```

EXAMPLOD Script

Sample 1. FOR Loop

The following example uses a simple FOR loop to insert ten rows into a database table. The values of a loop index, counter variable, and either of two character strings are inserted. Which string is inserted depends on the value of the loop index.

Input Table

Not applicable.

PL/SQL Block

-- available online in file SAMPLE1
DECLARE
  x NUMBER := 100;
BEGIN
  FOR i IN 1..10 LOOP
    IF MOD(i,2) = 0 THEN     -- i is even
      INSERT INTO temp VALUES (i, x, 'i is even');
    ELSE
      INSERT INTO temp VALUES (i, x, 'i is odd');
    END IF;
    x := x + 100;
  END LOOP;
  COMMIT;
END;

Output Table

SQL> SELECT * FROM temp ORDER BY col1;

<table>
<thead>
<tr>
<th>COL1</th>
<th>COL2</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>100</td>
<td>i is odd</td>
</tr>
<tr>
<td>2</td>
<td>200</td>
<td>i is even</td>
</tr>
<tr>
<td>3</td>
<td>300</td>
<td>i is odd</td>
</tr>
<tr>
<td>4</td>
<td>400</td>
<td>i is even</td>
</tr>
<tr>
<td>5</td>
<td>500</td>
<td>i is odd</td>
</tr>
<tr>
<td>6</td>
<td>600</td>
<td>i is even</td>
</tr>
<tr>
<td>7</td>
<td>700</td>
<td>i is odd</td>
</tr>
<tr>
<td>8</td>
<td>800</td>
<td>i is even</td>
</tr>
<tr>
<td>9</td>
<td>900</td>
<td>i is odd</td>
</tr>
<tr>
<td>10</td>
<td>1000</td>
<td>i is even</td>
</tr>
</tbody>
</table>

10 records selected.
Sample 2. Cursors

The next example uses a cursor to select the five highest paid employees from the emp table.

Input Table

SQL> SELECT ename, empno, sal FROM emp ORDER BY sal DESC;

<table>
<thead>
<tr>
<th>ENAME</th>
<th>EMPNO</th>
<th>SAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>KING</td>
<td>7839</td>
<td>5000</td>
</tr>
<tr>
<td>SCOTT</td>
<td>7788</td>
<td>3000</td>
</tr>
<tr>
<td>FORD</td>
<td>7902</td>
<td>3000</td>
</tr>
<tr>
<td>JONES</td>
<td>7566</td>
<td>2975</td>
</tr>
<tr>
<td>BLAKE</td>
<td>7698</td>
<td>2850</td>
</tr>
<tr>
<td>CLARK</td>
<td>7782</td>
<td>2450</td>
</tr>
<tr>
<td>ALLEN</td>
<td>7499</td>
<td>1600</td>
</tr>
<tr>
<td>TURNER</td>
<td>7844</td>
<td>1500</td>
</tr>
<tr>
<td>MILLER</td>
<td>7934</td>
<td>1300</td>
</tr>
<tr>
<td>WARD</td>
<td>7521</td>
<td>1250</td>
</tr>
<tr>
<td>MARTIN</td>
<td>7654</td>
<td>1250</td>
</tr>
<tr>
<td>ADAMS</td>
<td>7876</td>
<td>1100</td>
</tr>
<tr>
<td>JAMES</td>
<td>7900</td>
<td>950</td>
</tr>
<tr>
<td>SMITH</td>
<td>7369</td>
<td>800</td>
</tr>
</tbody>
</table>

14 records selected.

PL/SQL Block

-- available online in file SAMPLE2
DECLARE
    CURSOR c1 is
        SELECT ename, empno, sal FROM emp
            ORDER BY sal DESC;   -- start with highest paid employee
    my_ename CHAR(10);
    my_empno NUMBER(4);
    my_sal   NUMBER(7,2);
BEGIN
    OPEN c1;
    FOR i IN 1..5 LOOP
        FETCH c1 INTO my_ename, my_empno, my_sal;
        EXIT WHEN c1%NOTFOUND;  /* in case the number requested */
                          /* is more than the total */
                          /* number of employees */
        INSERT INTO temp VALUES (my_sal, my_empno, my_ename);
        COMMIT;
    END LOOP;
    CLOSE c1;
END;
Sample 3. Scoping

The following example illustrates block structure and scope rules. An outer block declares two variables named x and counter and loops four times. Inside this loop is a sub-block that also declares a variable named x. The values inserted into the temp table show that the two x’s are indeed different.

--- available online in file SAMPLE3

```sql
DECLARE
  x NUMBER := 0;
  counter NUMBER := 0;
BEGIN
  FOR i IN 1..4 LOOP
    x := x + 1000;
    counter := counter + 1;
    INSERT INTO temp VALUES (x, counter, 'outer loop');
  /* start an inner block */
  DECLARE
    x NUMBER := 0;  -- this is a local version of x
  BEGIN
    FOR i IN 1..4 LOOP
      x := x + 1;   -- this increments the local x
      counter := counter + 1;
      INSERT INTO temp VALUES (x, counter, 'inner loop');
    END LOOP;
  END;
  END LOOP;
END;
```
Output Table

<table>
<thead>
<tr>
<th>COL1</th>
<th>COL2</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000</td>
<td>1</td>
<td>OUTER loop</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>inner loop</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>inner loop</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>inner loop</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>inner loop</td>
</tr>
<tr>
<td>2000</td>
<td>6</td>
<td>OUTER loop</td>
</tr>
<tr>
<td>1</td>
<td>7</td>
<td>inner loop</td>
</tr>
<tr>
<td>2</td>
<td>8</td>
<td>inner loop</td>
</tr>
<tr>
<td>3</td>
<td>9</td>
<td>inner loop</td>
</tr>
<tr>
<td>4</td>
<td>10</td>
<td>inner loop</td>
</tr>
<tr>
<td>3000</td>
<td>11</td>
<td>OUTER loop</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>inner loop</td>
</tr>
<tr>
<td>2</td>
<td>13</td>
<td>inner loop</td>
</tr>
<tr>
<td>3</td>
<td>14</td>
<td>inner loop</td>
</tr>
<tr>
<td>4</td>
<td>15</td>
<td>inner loop</td>
</tr>
<tr>
<td>4000</td>
<td>16</td>
<td>OUTER loop</td>
</tr>
<tr>
<td>1</td>

<tr>
<td>3</td>
<td>19</td>
<td>inner loop</td>
</tr>
<tr>
<td>4</td>
<td>20</td>
<td>inner loop</td>
</tr>
</tbody>
</table>

20 records selected.

Sample 4. Batch Transaction Processing

In the next example the accounts table is modified according to instructions stored in the action table. Each row in the action table contains an account number, an action to be taken (I, U, or D for insert, update, or delete), an amount by which to update the account, and a time tag used to sequence the transactions.

On an insert, if the account already exists, an update is done instead. On an update, if the account does not exist, it is created by an insert. On a delete, if the row does not exist, no action is taken.
**Input Tables**

```
SQL> SELECT * FROM accounts ORDER BY account_id;

ACCOUNT_ID         BAL
––––––––––   –––––––––
 1      1000
 2      2000
 3      1500
 4      6500
 5       500

SQL> SELECT * FROM action ORDER BY time_tag;

ACCOUNT_ID  O  NEW_VALUE STATUS                   TIME_TAG
––––––––––  – –––––––––– –––––––––––––––––––––––– –––––––––

Sample 5. Embedded PL/SQL

The following example shows how you can embed PL/SQL in a high-level host language such as C and demonstrates how a banking debit transaction might be done.

**Input Table**

<table>
<thead>
<tr>
<th>ACCOUNT_ID</th>
<th>BAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1000</td>
</tr>
<tr>
<td>2</td>
<td>2000</td>
</tr>
<tr>
<td>3</td>
<td>1500</td>
</tr>
<tr>
<td>4</td>
<td>6500</td>
</tr>
<tr>
<td>5</td>
<td>500</td>
</tr>
</tbody>
</table>

**PL/SQL Block in a C Program**

```c
/* available online in file SAMPLE5 */
#include <stdio.h>
char     buf[20];
EXEC SQL BEGIN DECLARE SECTION;
INT     acct;
DOUBLE  debit;
DOUBLE  new_bal;
VARCHAR status[65];
VARCHAR uid[20];
VARCHAR pwd[20];
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLCA;
main()
{
    extern double atof();
    strcpy (uid.arr,"scott");
    uid.len=strlen(uid.arr);
    strcpy (pwd.arr,"tiger");
    pwd.len=strlen(pwd.arr);
    printf("\n\nEmbedded PL/SQL Debit Transaction Demo\n\n");
    printf("Trying to connect...");
    EXEC SQL WHENEVER SQLERROR GOTO errprint;
    EXEC SQL CONNECT :uid IDENTIFIED BY :pwd;
    printf(" connected.\n");
```
for (;;) /* Loop infinitely */
{
    printf("\n** Debit which account number? (-1 to end) ");
    gets(buf);
    acct = atoi(buf);
    if (acct == -1) /* Need to disconnect from Oracle */
    {                   /* and exit loop if account is -1 */
        EXEC SQL COMMIT RELEASE;
        exit(0);
    }
    printf(" What is the debit amount? ");
    gets(buf);
    debit = atof(buf);

    /**********************************************************/
    /* ----- Begin the PL/SQL block ----- */
    /**********************************************************/
    EXEC SQL EXECUTE
    DECLARE
        insufficient_funds EXCEPTION;
        old_bal NUMBER;
        min_bal NUMBER := 500;
    BEGIN
        SELECT bal INTO old_bal FROM accounts
            WHERE account_id = :acct;
            -- If the account doesn't exist, the NO_DATA_FOUND
            -- exception will be automatically raised.
        :new_bal := old_bal - :debit;
        IF :new_bal >= min_bal THEN
            UPDATE accounts SET bal = :new_bal
                WHERE account_id = :acct;
            INSERT INTO journal
            VALUES (:acct, 'Debit', :debit, SYSDATE);
            :status := 'Transaction completed.';
        ELSE
            RAISE insufficient_funds;
        END IF;
    COMMIT;
EXCEPTION
    WHEN NO_DATA_FOUND THEN

Sample 6. Calling a Stored Procedure

This Pro*C program connects to Oracle, prompts the user for a department number, then calls a procedure named `get_employees`, which is stored in a package named `personnel`. The procedure declares three PL/SQL tables as OUT formal parameters, then fetches a batch of employee data into the PL/SQL tables. The matching actual parameters are host arrays. When the procedure finishes, it automatically assigns all row values in the PL/SQL tables to corresponding elements in the host arrays. The program calls the procedure repeatedly, displaying each batch of employee data, until no more data is found.

**Input Table**

```
SQL> SELECT ename, empno, sal FROM emp ORDER BY sal DESC;

ENAME  EMPNO  SAL
------- ------- ----
KING    7839   5000
SCOTT   7788   3000
FORD    7902   3000
JONES   7566   2975
BLAKE   7698   2850
CLARK   7782   2450
ALLEN   7499   1600
TURNER  7844   1500
MILLER  7934   1300

This appendix explains the semantic differences between the CHAR and VARCHAR2 base types. These subtle but important differences come into play when you assign, compare, insert, update, select, or fetch character values.
Assigning Character Values

When you assign a character value to a CHAR variable, if the value is shorter than the declared length of the variable, PL/SQL blank-pads the value to the declared length. So, information about trailing blanks is lost. For example, given the following declaration, the value of `name` includes six trailing blanks:

```plsql
name CHAR(10) := 'CHEN ';  -- note trailing blank
```

If the character value is longer than the declared length of the CHAR variable, PL/SQL aborts the assignment and raises the predefined exception `VALUE_ERROR`. PL/SQL neither truncates the value nor tries to trim trailing blanks. For example, given the declaration

```plsql
acronym CHAR(4);
```

the following assignment raises `VALUE_ERROR`:

```plsql
acronym := 'SPCA';  -- note trailing blank
```

When you assign a character value to a VARCHAR2 variable, if the value is shorter than the declared length of the variable, PL/SQL neither blank-pads the value nor strips trailing blanks. Character values are assigned intact, so no information is lost. If the character value is longer than the declared length of the VARCHAR2 variable, PL/SQL aborts the assignment and raises `VALUE_ERROR`. PL/SQL neither truncates the value nor tries to trim trailing blanks.

Comparing Character Values

You can use the relational operators to compare character values for equality or inequality. Comparisons are based on the collating sequence used for the database character set. One character value is greater than another if it follows it in the collating sequence. For example, given the declarations

```plsql
name1 VARCHAR2(10) := 'COLES';
name2 VARCHAR2(10) := 'COLEMAN';
```

the following IF condition is TRUE:

```plsql
IF name1 > name2 THEN ...
```
ANSI/ISO SQL requires that two character values being compared have equal lengths. So, if both values in a comparison have datatype CHAR, *blank-padding* semantics are used. That is, before comparing character values of unequal length, PL/SQL blank-pads the shorter value to the length of the longer value. For example, given the declarations

```sql
name1 CHAR(5) := 'BELLO';
name2 CHAR(10) := 'BELLO   '; -- note trailing blanks
```

the following IF condition is TRUE:

```sql
IF name1 = name2 THEN ... 
```

If either or both values in a comparison have datatype VARCHAR2, *non-blank-padding* semantics are used. That is, when comparing character values of unequal length, PL/SQL makes no adjustments and uses the exact lengths. For example, given the declarations

```sql
name1 VARCHAR2(10) := 'DOW';
name2 VARCHAR2(10) := 'DOW   '; -- note trailing blanks
```

the following IF condition is FALSE:

```sql
IF name1 = name2 THEN ... 
```

As expected, if one value in a comparison has datatype VARCHAR2 and the other value has datatype CHAR, non-blank-padding semantics are used. But, remember, when you assign a character value to a CHAR variable, if the value is shorter than the declared length of the variable, PL/SQL blank-pads the value to the declared length. So, given the declarations

```sql
name1 VARCHAR2(10) := 'STAUB';
name2 CHAR(10) := 'STAUB'; -- PL/SQL blank-pads value
```

the following IF condition is FALSE because the value of `name2` includes five trailing blanks:

```sql
IF name1 = name2 THEN ... 
```

All string literals have datatype CHAR. So, if both values in a comparison are literals, blank-padding semantics are used. If one value is a literal, blank-padding semantics are used only if the other value has datatype CHAR.
Inserting Character Values

When you insert the values of a PL/SQL character variable into an Oracle database column, whether they are blank-padded or not depends on the column type, not on the variable type.

When you insert a character value into a CHAR database column, Oracle does not strip trailing blanks. If the value is shorter than the defined width of the column, Oracle blank-pads the value to the defined width. As a result, information about trailing blanks is lost. If the character value is longer than the defined width of the CHAR column, Oracle aborts the insert and generates an error.

When you insert a character value into a VARCHAR2 database column, Oracle does not strip trailing blanks. If the value is shorter than the defined width of the column, Oracle does not blank-pad the value. Character values are stored intact, so no information is lost. If the character value is longer than the defined width of the VARCHAR2 column, Oracle aborts the insert and generates an error.

The same rules apply when updating.

Selecting Character Values

When you select values from an Oracle database column into a PL/SQL character variable, whether they are blank-padded or not depends on the variable type, not on the column type.

When you select a column value into a CHAR variable, if the value is shorter than the declared length of the variable, PL/SQL blank-pads the value to the declared length. As a result, information about trailing blanks is lost. If the character value is longer than the declared length of the CHAR variable, PL/SQL aborts the assignment and raises VALUE_ERROR.

When you select a column value into a VARCHAR2 variable, if the value is shorter than the declared length of the variable, PL/SQL neither blank-pads the value nor strips trailing blanks. Character values are stored intact, so no information is lost. For example, when you select a blank-padded CHAR column value into a VARCHAR2 variable, the trailing blanks are not stripped. If the character value is longer than the declared length of the VARCHAR2 variable, PL/SQL aborts the assignment and raises VALUE_ERROR.

The same rules apply when fetching.
In a given execution environment, whether CHAR is equivalent to VARCHAR2 or not is determined by a command or option that sets Oracle Version 6 or Oracle7 compatibility. For example, in the SQL*Plus environment, you issue the SET COMPATIBILITY command, specifying the value V6 or V7 (the default), as follows:

```
SQL> SET COMPATIBILITY V6
```

For another example, in the Oracle Precompiler environment, you specify the runtime option DBMS on the command line, as follows:

```
... DBMS=V6 ...
```

The default value is NATIVE, which specifies the version of Oracle resident on your system, which must be version 6 or later.

When selecting data over a V7–to–V6 link, use VARCHAR2 variables in the WHERE clause instead of CHAR variables. Otherwise, you might get an unsupported network datatype error.

When INSERTing character values, you can ensure that no trailing blanks are stored by using the RTRIM function, which trims trailing blanks. An example follows:

```sql
my_empno := 7471;
my_ename := 'LEE  '; -- note trailing blanks
...
INSERT INTO emp
    VALUES (my_empno, RTRIM(my_ename), ...); -- inserts 'LEE'
```
This appendix shows you how to run the PL/SQL Wrapper, a standalone utility that converts PL/SQL source code into portable object code. You can use the Wrapper to deliver PL/SQL applications without exposing your source code.
Advantages of Wrapping

The PL/SQL Wrapper converts PL/SQL source code into an intermediate form of object code. By hiding application internals, the Wrapper prevents

- misuse of your application by other developers
- exposure of your algorithms to business competitors

Wrapped code is as portable as source code. The PL/SQL compiler recognizes and loads wrapped compilation units automatically. Other advantages include

- platform independence—you need not deliver multiple versions of the same compilation unit
- dynamic loading—users need not shut down and relink to add a new feature
- dynamic binding—external references are resolved at load time
- strict dependency checking—invalidated program units are recompiled automatically
- normal importing and exporting—the Import/Export utility accepts wrapped files

Running the PL/SQL Wrapper

To run the PL/SQL Wrapper, enter the WRAP command at your system prompt using the following syntax:

`WRAP INAME=input_file [ONAME=output_file]`

You can use uppercase or lowercase. Leave no space around the equal signs because spaces delimit individual arguments.

The WRAP command requires only one argument, which is

`INAME=input_file`

where `input_file` is the path and name of the Wrapper input file. You need not specify the file extension because it defaults to `sql`. For example, the following commands are equivalent:

`WRAP INAME=/mydir/myfile`
`WRAP INAME=/mydir/myfile.sql`
However, you can specify a different file extension as the following example shows:

WRAP INAME=/mydir/myfile.src

Optionally, the WRAP command takes a second argument, which is

ONAME=output_file

where output_file is the path and name of the Wrapper output file. You
need not specify the output file because its name defaults to that of the
input file and its extension defaults to plb (PL/SQL binary). For
example, the following commands are equivalent:

WRAP INAME=/mydir/myfile
WRAP INAME=/mydir/myfile.sql ONAME=/mydir/myfile.plb

However, you can use the option ONAME to specify a different file
name and extension, as the following example shows:

WRAP INAME=/mydir/myfile ONAME=/yourdir/yourfile.obj

**Input and Output Files**

The input file can contain any combination of SQL statements. However,
the PL/SQL Wrapper wraps only the following CREATE statements,
which define PL/SQL packages and standalone subprograms:

- CREATE [OR REPLACE] PACKAGE
- CREATE [OR REPLACE] PACKAGE BODY
- CREATE [OR REPLACE] FUNCTION
- CREATE [OR REPLACE] PROCEDURE

All other SQL statements are passed intact to the output file. Comment
lines (beginning with REM or --) are deleted unless they appear in a
package or subprogram definition.

A wrapped package or subprogram definition has the form

<header> WRAPPED <body>

where header begins with the reserved word CREATE and ends with the
name of the package or subprogram, and body is an intermediate form of
object code that looks like a random sequence of characters. The
keyword WRAPPED tells the PL/SQL compiler that the package or
subprogram is wrapped.
The header can contain comments. For example, the Wrapper converts

```
CREATE OR REPLACE PACKAGE
-- Author: J Smith
-- Date:   11/15/94
mypkg AS ... 
```

into

```
CREATE OR REPLACE PACKAGE
-- Author: J Smith
-- Date:   11/15/94
mypkg WRAPPED 8c724af33 ... 
```

Generally, the output file is much larger than the input file.

**Error Detection**

If your input file contains syntactic errors, the PL/SQL Wrapper detects and reports them. However, the Wrapper cannot detect semantic errors because it does not resolve external references. That is done at compile time. So, only the PL/SQL compiler can detect semantic errors.
Reserved Words

The words listed in this appendix are reserved by PL/SQL; that is, they have a special syntactic meaning to PL/SQL. So, you cannot use them to name program objects such as constants, variables, or cursors. Some of these words (marked by an asterisk) are also reserved by SQL. So, you cannot use them to name database objects such as columns, tables, or indexes.

ROWNUM, 4 – 5
pseudoinstruction, 5 – 9
pseudotype. See VARCHAR pseudotype
public object, 7 – 13
Q
qualifier
  using subprogram name as, 2–25
  when needed, 2–23, 2–26
quoted identifier, 2–6

R
RAISE statement, 5–12, 9–93
  using in exception handler, 5–16
raise_application_error procedure, 5–10
raising an exception, 5–12
RAW datatype, 2–13
  converting, 2–18
  maximum length, 2–14
read consistency, 4–35, 4–40
READ ONLY parameter, 4–40, 9–110
read-only transaction, 4–40
readability, 3–17
REAL subtype, 2–11
real_number, 9–65
record, 2–44, 9–94
  advantages, 2–48
  assignment, 2–46
  declaring, 2–44
  implicit declaration, 4–15
  initializing, 2–45
  nesting, 2–47
  referencing, 2–45
  %ROWTYPE, 4–15
  scope, 2–45
  syntax diagram, 9–94
RECORD datatype, 2–44
record.field, 9–7
record_declaration, 9–12, 9–53, 9–83, 9–90
record_name, 9–45, 9–72, 9–95, 9–108
recursion, 6–23
  infinite, 6–23
  mutual, 6–26
  terminating condition, 6–23
  versus iteration, 6–27
REF CURSOR datatype, 4–18
ref_cursor_type, 9–27
reference type, 2–9
relational operator, 2–31
relational_operator, 9–21
REPEAT UNTIL structure, mimicking, 3–8
REPLACE function, treatment of nulls, 2–36
reraising an exception, 5–15
reserved words, E–1
  misuse of, 2–5
  using as quoted identifier, 2–6
rest_of_select_statement, 9–108
RESTRICT_REFERENCES pragma, A–2
result value, function, 6–5
RETURN clause, 9–24, 9–28
  cursor, 4–14
  function, 6–5
RETURN reserved word, 9–52
RETURN statement, 6–7, 9–98
return type, 4–14, 4–18, 6–20
reusability, 6–3
REVERSE reserved word, 3–10, 9–72
rollback
  purpose, 4–36
  statement–level, 4–38
ROLLBACK reserved word, 9–100
rollback segment, 4–35
ROLLBACK statement, 4–37, 9–100
  effect on savepoints, 4–38
    implicit, 4–39
row lock, 4–41
row operator, 4–6
%ROWCOUNT cursor attribute, 9–102
  using with explicit cursor, 4–30
  using with implicit cursor, 4–33
rowid, 2–14
ROWID datatype, 2–14
ROWID pseudocolumn, 4–4
  using to mimic CURRENT OF clause, 4–43
ROWIDTOCHAR function, 4–5
ROWLABEL column, 4–5
ROWNUNM pseudocolumn, 4–5
%ROWTYPE attribute, 9–104
  using in record declaration, 2–20
ROWTYPE_MISMATCH exception, 5 – 6
RPC (remote procedure call), 5 – 13
RTRIM function, using to insert data, C – 5
runtime error, 5 – 1

S
sample database table
DEPT table, ix
EMP table, ix
sample programs, B – 1
savepoint name, reusing, 4 – 39
SAVEPOINT reserved word, 9 – 100
SAVEPOINT statement, 4 – 38, 9 – 106
savepoint_name, 9 – 100, 9 – 106
scalar type, 2 – 9
scale, specifying, 2 – 11
scheme, iteration, 3 – 10
scientific notation, 2 – 7
scope, 2 – 25
cursor, 4 – 10
cursor parameter, 4 – 11
cursor variable, 4 – 19
definition, 2 – 25

WORK reserved word, 9 – 100

Z

ZERO_DIVIDE exception, 5 – 7
Reader’s Comment Form

PL/SQL User’s Guide and Reference
Part No. A19486–2

Oracle Corporation welcomes your comments and suggestions on the quality and usefulness of this publication. Your input is an important part of the information used for revision.

- Did you find any errors?
- Is the information clearly presented?
- Do you need more information? If so, where?
- Are the examples correct? Do you need more examples?
- What features did you like most about this manual?

If you find any errors or have any other suggestions for improvement, please indicate the topic, chapter, and page number below:
